There are 41 predictors and 1 target variable (imdb_score). All of them match their expected data types, so there's no need to modify the datatype for any feature.

drop some columns

First we drop some columns that we won't use in our model at all. After getting rid of the titles, urls, and plot_keywords, there're 38 predictors and the target variable imdb_score.

```
df$movie_title <- NULL
df$imdb_link <- NULL
df$plot_keywords <- NULL

dim(df)
```

```
## [1] 1930   39
```

Business questions to explore through EDA Before jumping into EDA analysis, we've outlined some business questions to guide us through the process. By answering these questions, we hope to uncover insights that will inform our feature selection and interactions, potentially improving the performance of our predictive model.

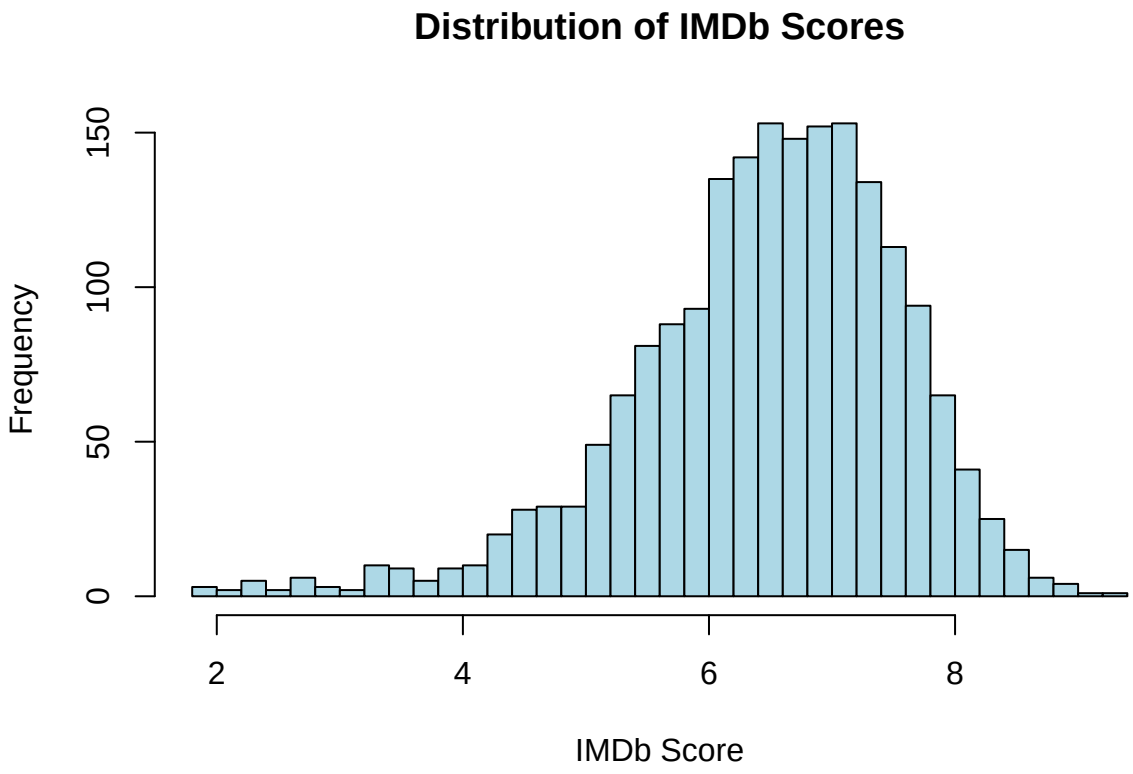
- What predictors have high correlation with IMDb scores? Is there any possible collinearity between predictors?
- Does the release timing affect IMDb scores?
- How does the combination of multiple genres in a movie affect its IMDb score?
- How does genre popularity differ across regions?
- How does the presence of top 10 personnel impact IMDb scores?
- Look into movies associated with the top 10 personnel for each predictor. Do different personnel associate with certain countries? What types of movie genres tend to have the highest average IMDb scores among these top personnel?

We will explore these questions in our upcoming analysis. By doing so, we aim to gain deeper insights into the relationships between features. This will help us determine which interactions between variables are worth including in our model to improve model performance.

High-level veiw of dataset To get a feel for the dataset, first we look at shape of the target.

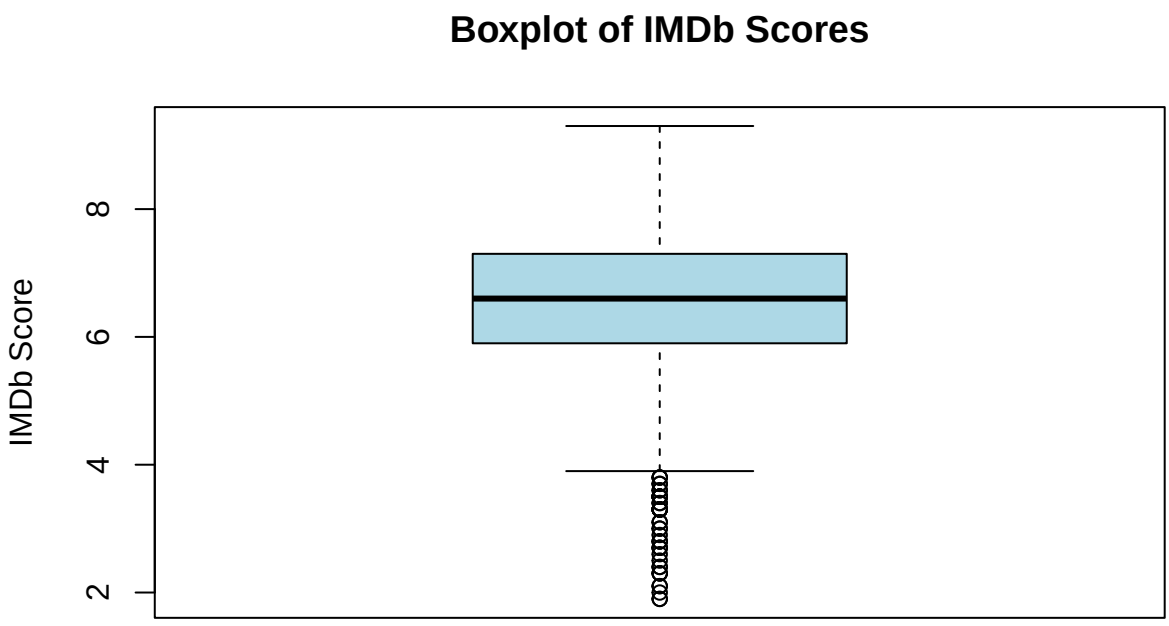
Target variable: imdb_score histogram

```
hist(df$imdb_score, main = "Distribution of IMDb Scores", xlab = "IMDb Score", col = "lightblue", breaks
```



boxplot

```
boxplot(df$imdb_score, main = "Boxplot of IMDb Scores", ylab = "IMDb Score", col = "lightblue")
```



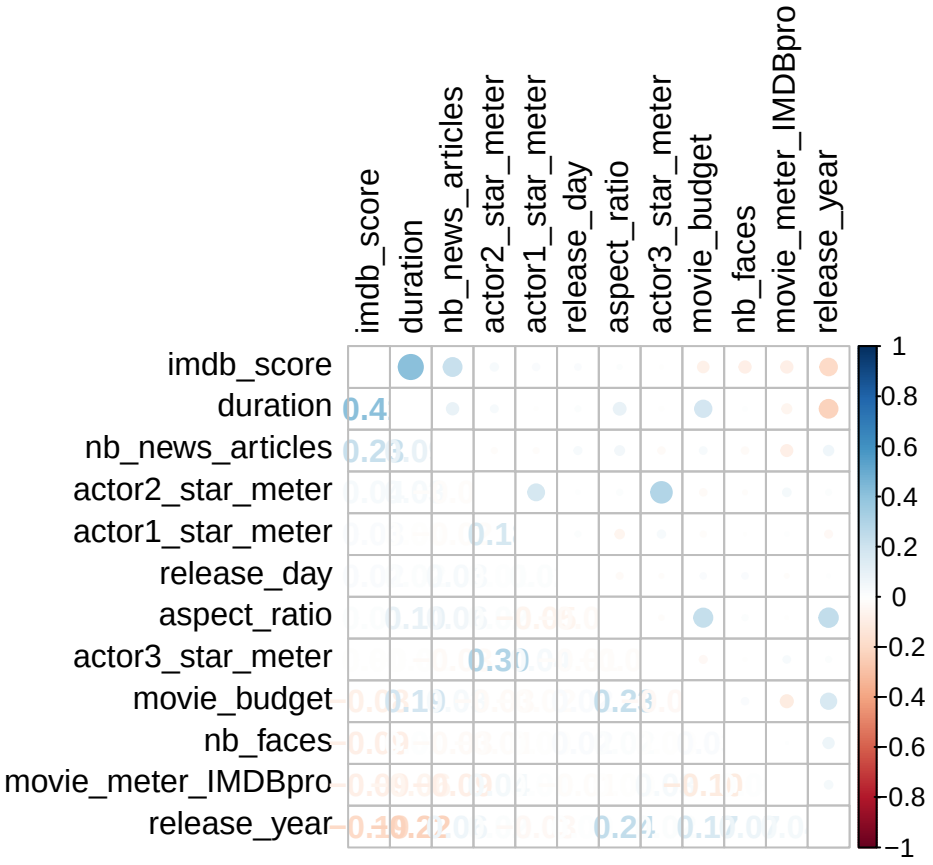
The IMDb Scores are slightly left-skewed, but it's not severe enough to be a major concern. This distribution makes sense because people usually rate good movies higher while reserving lower ratings for particularly bad experiences, which are less common. Since many viewers are more inclined to watch movies they expect to enjoy, this could lead to higher overall ratings.

Numerical predictors For numerical variables, we first looking at their correlations and distribution.

Correlations with imdb_score

```
numerical_cols <- df[, c("imdb_score", "movie_budget", "release_day", "release_year", "duration",
                         "aspect_ratio", "nb_news_articles", "actor1_star_meter", "actor2_star_meter",
                         "actor3_star_meter", "nb_faces", "movie_meter_IMDBpro")]

cor_matrix <- cor(numerical_cols, use = "pairwise.complete.obs")
# sort on decreasing correlations with imdb_score
cor_sorted <- cor_matrix[order(-cor_matrix[, "imdb_score"]), order(-cor_matrix["imdb_score", ])]
# plot it
corrplot.mixed(cor_sorted, tl.col = "black", tl.pos = "lt")
```



Scatter plot matrix

```
options(scipen=999)

ggpairs(df[c("imdb_score", colnames(numerical_cols))],
        upper = list(continuous = wrap("cor", size = 4)),
        lower = list(continuous = wrap("points", alpha = 0.6)),
        diag = list(continuous = "barDiag"),
        progress = FALSE, message = FALSE, warnings = FALSE)
```

```
## Warning in warn_if_args_exist(list(...)): Extra arguments: 'message',
## 'warnings' are being ignored.  If these are meant to be aesthetics, submit them
## using the 'mapping' variable within ggpairs with ggplot2::aes or
## ggplot2::aes_string.
```

```
## `stat_bin()` using `bins = 30`. Pick better value with `binwidth`.
## `stat_bin()` using `bins = 30`. Pick better value with `binwidth`.
```

```
## `stat_bin()` using `bins = 30`. Pick better value with `binwidth`.

## `stat_bin()` using `bins = 30`. Pick better value with `binwidth`.
## `stat_bin()` using `bins = 30`. Pick better value with `binwidth`.
## `stat_bin()` using `bins = 30`. Pick better value with `binwidth`.
## `stat_bin()` using `bins = 30`. Pick better value with `binwidth`.
## `stat_bin()` using `bins = 30`. Pick better value with `binwidth`.
## `stat_bin()` using `bins = 30`. Pick better value with `binwidth`.
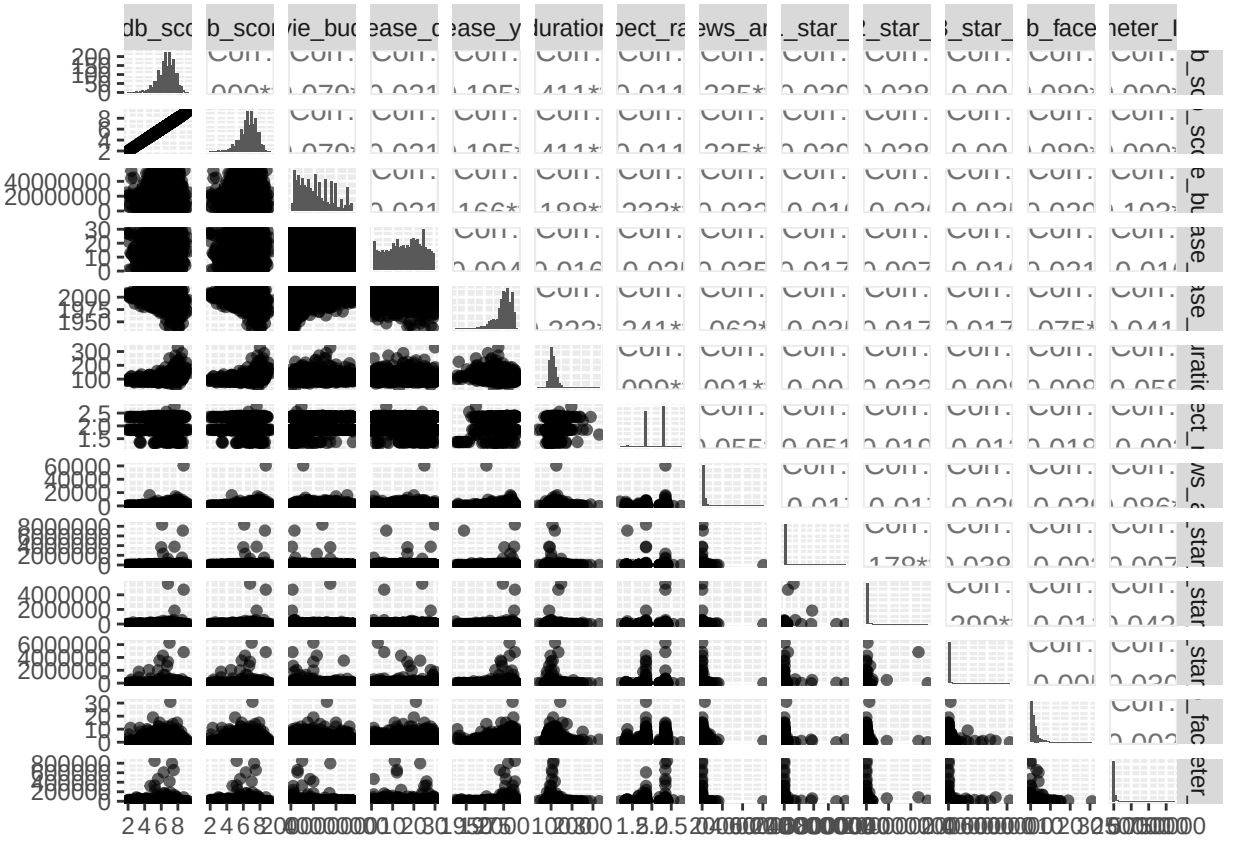
```



There is a moderate positive correlation between movie duration and IMDb score. This suggests that longer movies tend to have slightly higher ratings on average. Overall, the correlations shown above are quite low, no matter it's between target or predictors themselves.

Note: Since Pearson's correlation only captures linear relationships, non-linear interactions between certain variables and IMDb scores might exist.

Categorical predictors For categorical variables, we first look at the dummy variables to see their distributions and correlations. Since some categorical variables in string format may require further conversion and can be more complex, we'll address those in the later sections and explore them in more detail then.

Dummy variables - genres

1. bar chart

There're imbalances presenting in some predictors.

```r
par(mfrow = c(5, 3), mar = c(2, 2, 2, 2))

genre_columns <- colnames(df)[grepl("action|adventure|scifi|thriller|musical|romance|western|sport|horro

for (genre in genre_columns) {

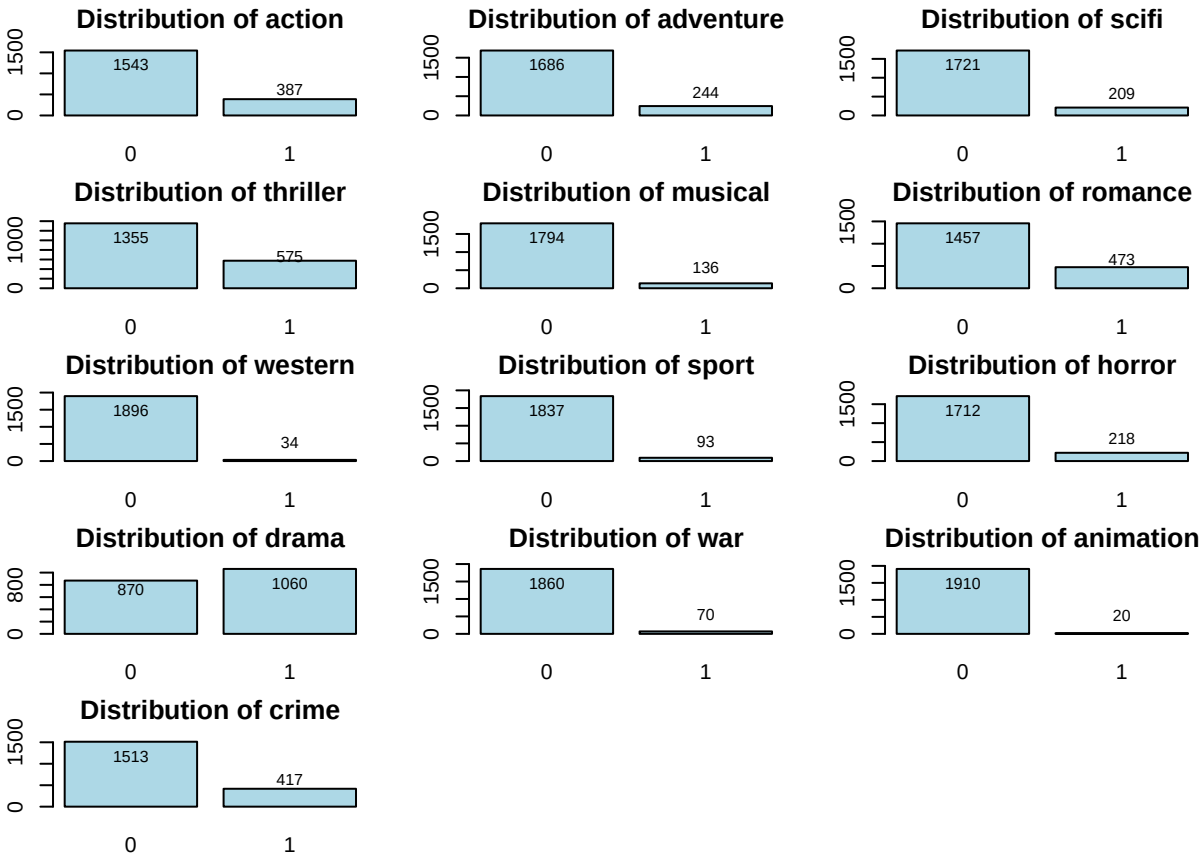
  genre_counts <- table(df[[genre]])

  bar_heights <- barplot(genre_counts, main = paste("Distribution of", genre), col = "lightblue", ylim =

  text(x = bar_heights, y = genre_counts / 2, labels = genre_counts, cex = 0.8, col = "black", pos = 3)

}

par(mfrow = c(1, 1), mar = c(5, 4, 4, 2) + 0.1)
```



2. Boxplots

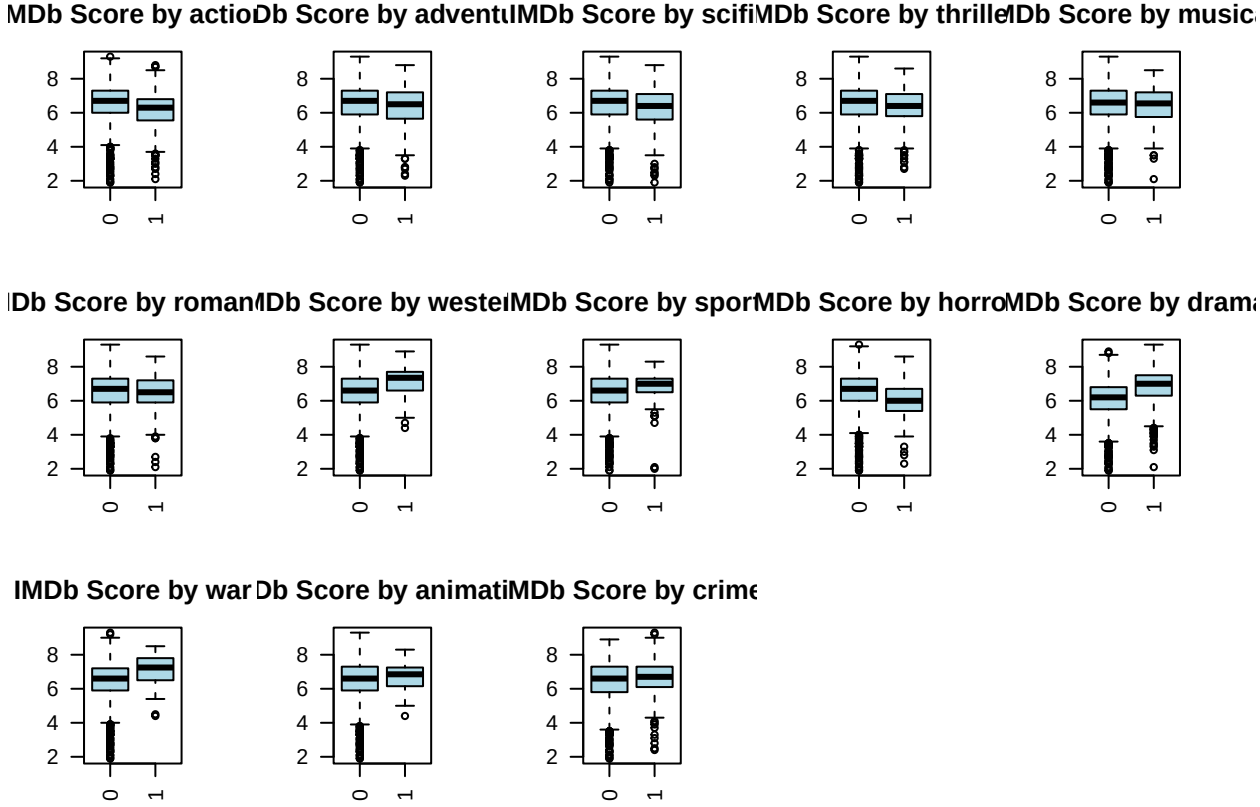
Some genres show insignificant differences in terms of ratings, indicating that we might consider dropping them from our analysis.

```r
par(mfrow = c(3, 5), mar = c(3, 3, 3, 3))

for (genre in genre_columns) {
  boxplot(df$imdb_score ~ df[[genre]],
          main = paste("IMDb Score by", genre),
          ylab = "IMDb Score",
```

```
          xlab = genre,
          col = "lightblue",
          las = 2)  # las = 2 makes the axis labels perpendicular to the axis
}

par(mfrow = c(1, 1), mar = c(5, 4, 4, 2) + 0.1)
```



3. Point Biserial Correlation

*** specifically suited for binary-continuous relationships, it measures the strength and direction of the association between a binary variable and a continuous variable.

Drama has the strongest positive correlation with IMDb score, suggesting drama movies tend to be rated higher than average.

```
for (genre in genre_columns) {
  correlation <- biserial(df$imdb_score, df[[genre]])
  print(paste(genre, ":", correlation))
}
```

```

EDA - categorical predictors This section focuses on the essential task of cleaning and addressing any imperfections for later analysis, specifically for categorical predictors. We review all the features, addressing them one by one. This process includes handling missing values, converting variable types, encoding, and performing feature extractions.

Language Because the test dataset has no variation in this predictor (all movies are in English), it doesn't provide useful information for predicting IMDb scores. So, we decide to drop it.

(skip the following analysis)

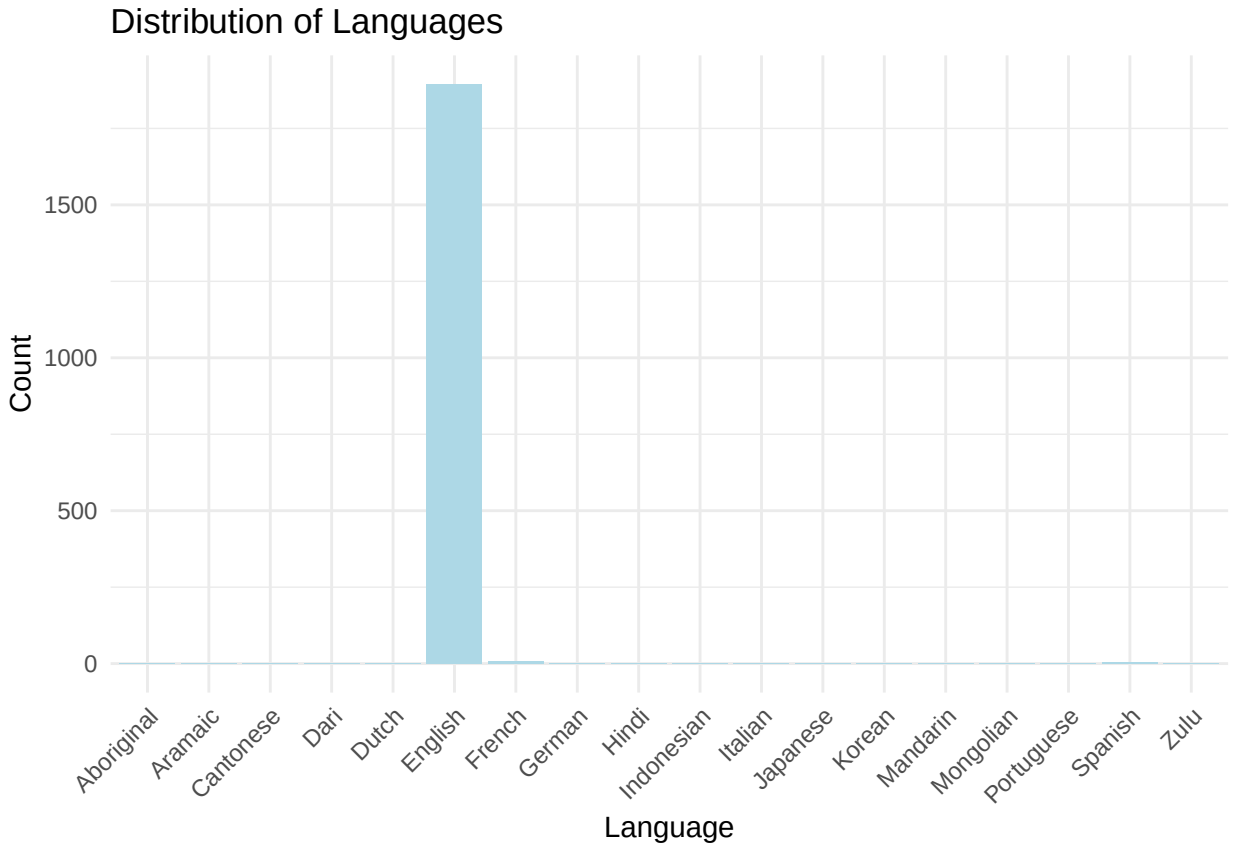
Since the two missing movies are from the North America region, it's reasonable to impute their language as English.

```
df$language[df$language == "None"] <- "English"
nrow(df[df$language == "" | df$language == "NaN" | df$language == "None", ]) # 0
```

```
## [1] 0
```

bar plot

```
ggplot(df, aes(x = language)) +
  geom_bar(fill = "lightblue") +
  labs(title = "Distribution of Languages", x = "Language", y = "Count") +
  theme_minimal() +
  theme(axis.text.x = element_text(angle = 45, hjust = 1))
```

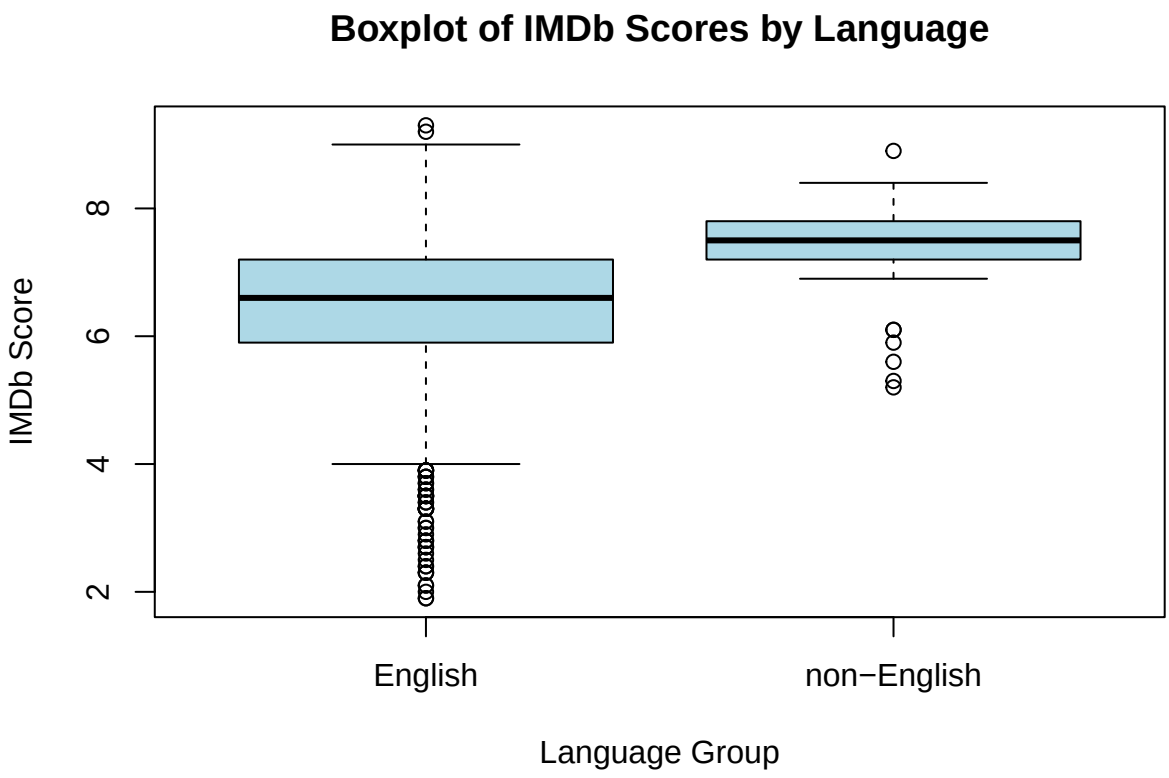


Since this column has an imbalanced distribution, with many granular languages that have little impact on the model, it would be better to group all non-English languages into a 'Non-English' category. This approach can simplify the model while still preserving important information about the language factor by keeping only 'English' and 'Non-English'.

```
df$language[df$language != "English"] <- "non-English"
```

box plot

```
boxplot(imdb_score ~ language, data = df, main = "Boxplot of IMDb Scores by Language",
        xlab = "Language Group", ylab = "IMDb Score", col = "lightblue")
```



```
table(df$language)
```

```
##
##     English non-English
##        1894          36
```

The boxplot suggests a significant difference in IMDb scores between English and non-English movies. A pairwise t-test can formally determine whether this new classification is effective by assessing the impact of language on IMDb scores. If we reject the null hypothesis, it indicates that language could be a significant predictor of IMDb scores.

pairwise t-test

(Conservative ranking: Scheffé > Bonferroni > Tukey > Fisher's LSD)

We choose a middle conservative t-test approach (Bonferroni), to assess the robustness of the newly reclassified levels.

```
pairwise_results <- pairwise.t.test(df$imdb_score, df$language, p.adjust.method = "bonferroni")
print(pairwise_results)
```

```
##
##  Pairwise comparisons using t tests with pooled SD
##
## data:  df$imdb_score and df$language
##
##             English
## non-English 0.00001
##
## P value adjustment method: bonferroni
```

This result indicates that there is a statistically significant difference in the mean IMDb scores between English and non-English movies, concluding that the language classification impacts the IMDb score.

Genres Split the string format genres and remove duplicate ones with dummy.

Steps:

1. Splitting the genres and storing in a new column as a list
2. Identify unique genres from "Genres" after splitting
3. Filter out genres that aren't represented as columns
4. Create new dummified columns for those extracted, unique genres
5. Assign 1 / 0 to these new dummy variables corresponding to extracted genres list in each movie

Splitting the genres and storing in a new column as a list

```
df$genre_list <- strsplit(as.character(df$genres), "\\|")
head(df$genre_list)
```

```
## [[1]]
## [1] "Drama"
##
## [[2]]
## [1] "Biography" "Drama"     "Sport"
##
## [[3]]
## [1] "Drama" "Sport"
##
## [[4]]
## [1] "Horror"   "Thriller"
##
## [[5]]
## [1] "Biography" "Crime"     "Drama"
##
## [[6]]
## [1] "Comedy"  "Romance"
```

Identify unique genres from "Genres" after splitting

```
unique_genres <- tolower(unique(unlist(df$genre_list)))
unique_genres
```

```
##  [1] "drama"       "biography"   "sport"       "horror"      "thriller"
##  [6] "crime"       "comedy"      "romance"     "adventure"   "sci-fi"
## [11] "action"      "music"       "fantasy"     "history"     "mystery"
## [16] "family"      "war"         "musical"     "western"     "animation"
## [21] "documentary"
```

Filter out genres that aren't represented as columns

```
existing_genre_columns <- colnames(df)[colnames(df) %in% unique_genres]
existing_genre_columns
```

```
##  [1] "action"    "adventure" "thriller"  "musical"   "romance"   "western"
##  [7] "sport"     "horror"    "drama"     "war"       "animation" "crime"
```

Create new dummified columns for those extracted unique genres

&

Assign 1 / 0 to these new dummy variables corresponding to extracted genres list in each movie

```r
for (genre in unique_genres) {

  if (!(genre %in% existing_genre_columns)) {

    df[[genre]] <- sapply(df$genre_list, function(x) ifelse(str_to_title(genre) %in% x, 1, 0))

  }
}

df$genre_list <- NULL

head(df)
```

```

```

Look at the t-test to further filter out genres types that could be grouped together!

```
for (genre in genres_all) {
  # Welch's t-test
  t_test_results <- t.test(df$imdb_score[df[[genre]] == 1], df$imdb_score[df[[genre]] == 0])

  # Fetch and print insignificant genres (threshold: p-value = 0.05)
  if (t_test_results$p.value >= 0.05) {
    print(paste(genre, "- p-value:", t_test_results$p.value))
  }
}
```

```
## [1] "musical - p-value: 0.337662947281095"
## [1] "romance - p-value: 0.475827407419031"
## [1] "animation - p-value: 0.420847318364638"
## [1] "music - p-value: 0.0939739158062037"
## [1] "mystery - p-value: 0.863901049829263"
```

Group those undesired genres into “other_genres”

```
grouped_genres <- c("animation", "documentary", "musical", "romance", "music", "mystery")

df$other_genre <- 0

for (col in grouped_genres) {
  df$other_genre[df[[col]] == 1] <- 1
}

drop_genres_cols <- c("genres", "animation", "documentary", "musical", "romance", "music", "mystery")

df[drop_genres_cols] <- NULL

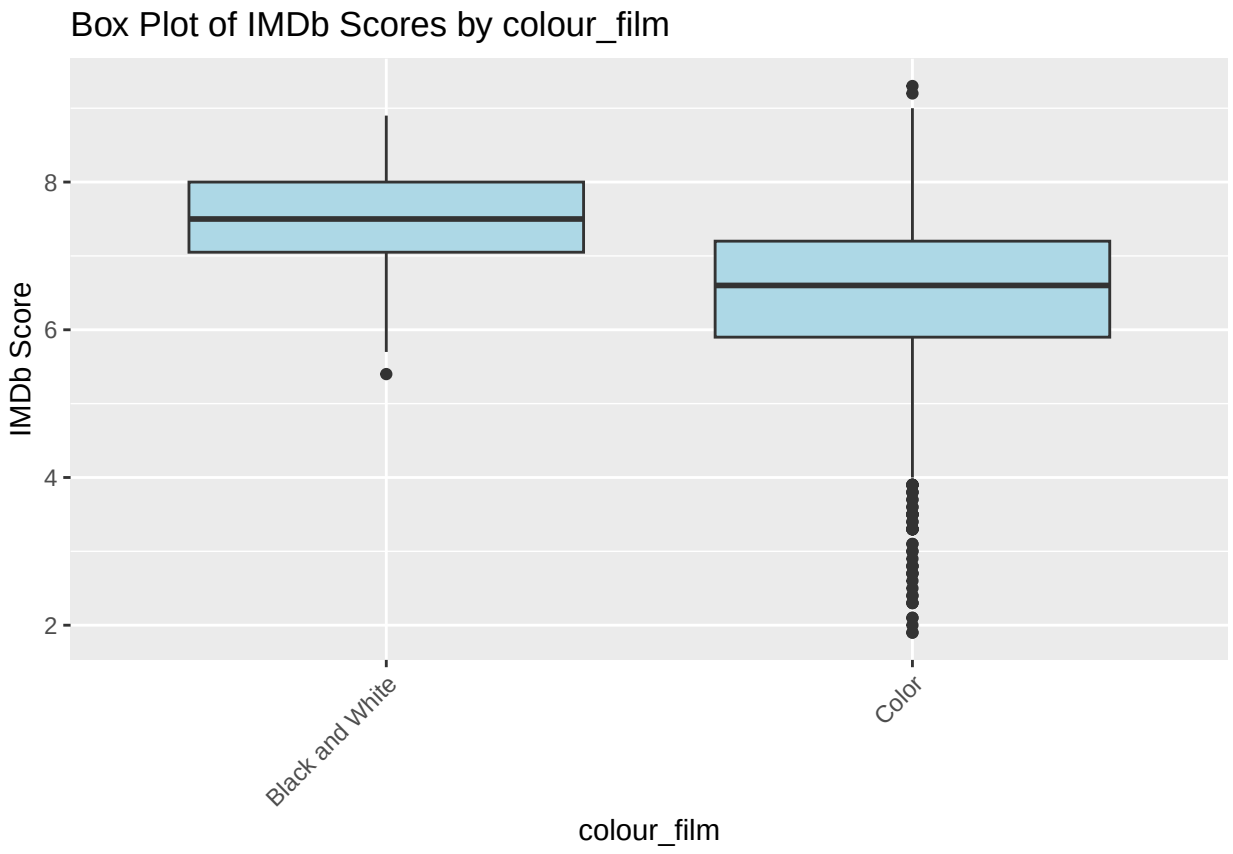
Color Film Because the test dataset has no variation in this predictor (all movies are in colour), it doesn't provide useful information for predicting IMDb scores. So, we decide to drop it.

(skip the following analysis)

There is a significant difference between the levels. Although the movies we are going to predict are all in color, making it reasonable to drop this variable, for now, we'll keep it to check its interaction effect with other predictors.

```
ggplot(df, aes(x = colour_film, y = imdb_score)) +
  geom_boxplot(fill = "lightblue") +
  labs(title = "Box Plot of IMDb Scores by colour_film",
       x = "colour_film",
       y = "IMDb Score") +
  theme(axis.text.x = element_text(angle = 45, hjust = 1))
```

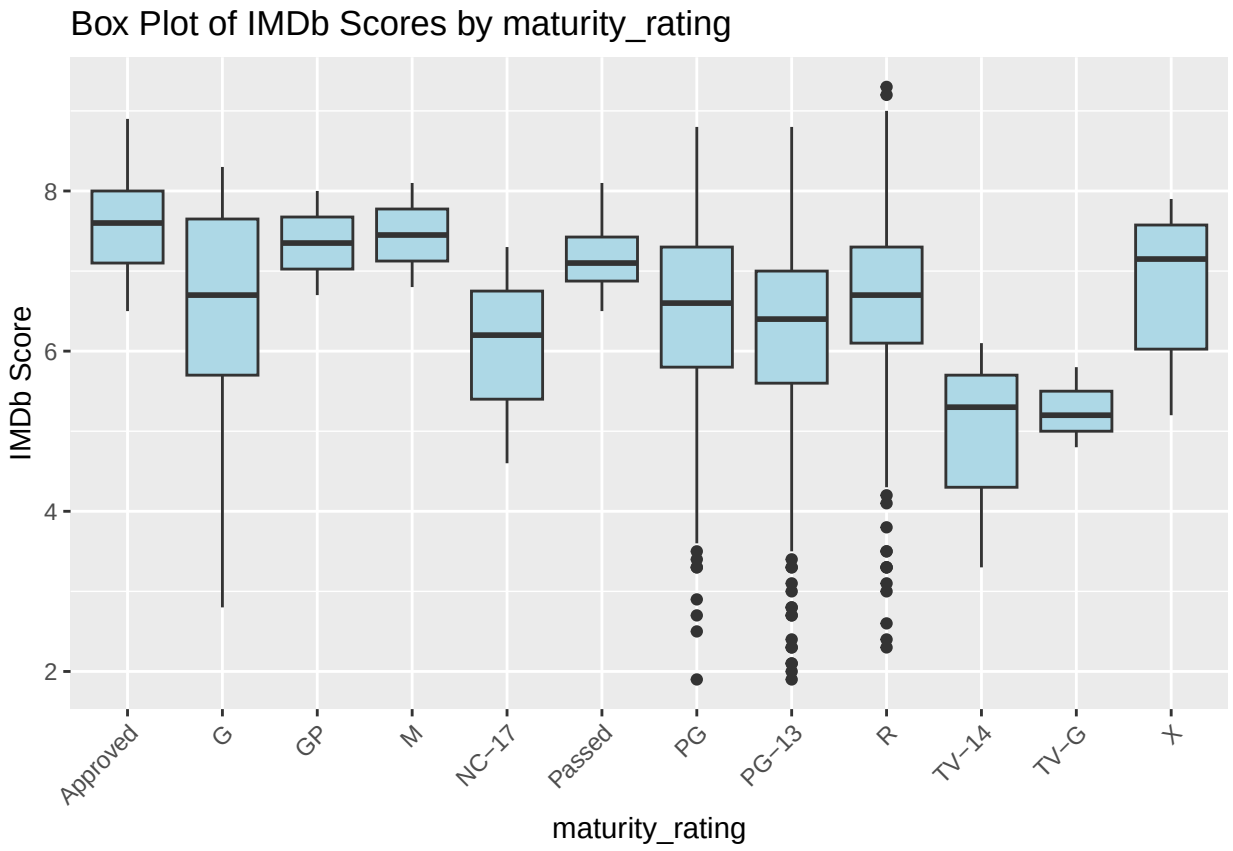


maturity_rating

- Approved: Generally used for older content (suitable for all ages, but often lacks specificity).
- G (General Audience) / TV-G (General Audience): Suitable for all ages (0+).
- GP (General Parental Guidance): Suggested parental guidance (ages 5+).
- PG (Parental Guidance): Some material may not be suitable for children (ages 7+).

- PG-13 (Parents Strongly Cautioned): Some material may be inappropriate for children under 13 (ages 13+).
- TV-14 (Parents Strongly Cautioned): Some material may be inappropriate for children under 14 (ages 14+).
- R (Restricted): Restricted to viewers over 17 or 18, parents are strongly cautioned (ages 17+).
- NC-17 (No One 17 and Under Admitted): Explicit content, unsuitable for minors (ages 17+).
- M (Mature): Content for mature audiences only (typically ages 17+).
- X (Adult Only): Explicit content, suitable for adults only (ages 18+).
- Passed: A classification indicating acceptance, typically seen in older content.

```
ggplot(df, aes(x = maturity_rating, y = imdb_score)) +
  geom_boxplot(fill = "lightblue") +
  labs(title = "Box Plot of IMDb Scores by maturity_rating",
       x = "maturity_rating",
       y = "IMDb Score") +
  theme(axis.text.x = element_text(angle = 45, hjust = 1))
```



Given the presence of rare levels in this feature, we reclassify them into three categories based on the age definitions mentioned earlier to help with dimension reduction and enhance the robustness of the levels.

```
table(df$maturity_rating)
```

```
##
## Approved        G       GP        M    NC-17   Passed       PG    PG-13
##       21       34        2        2        3        4      255      582
##        R    TV-14     TV-G        X
##     1013        3        3        8
```

Ordinal Levels -

Based on the usual rating hierarchy, the sorted ordinal levels for maturity ratings could be:

- $<$ 7 yo: Approved, G, TV-G, GP
- $<$ 17/18 yo: PG, PG-13, TV-14
- $=$ 17/18: R, NC-17, M, Passed, X

```
group_G <- c("Approved", "TV-G", "GP")
group_PG <- c("PG-13", "TV-14")
group_R <- c("NC-17", "M", "Passed", "X")

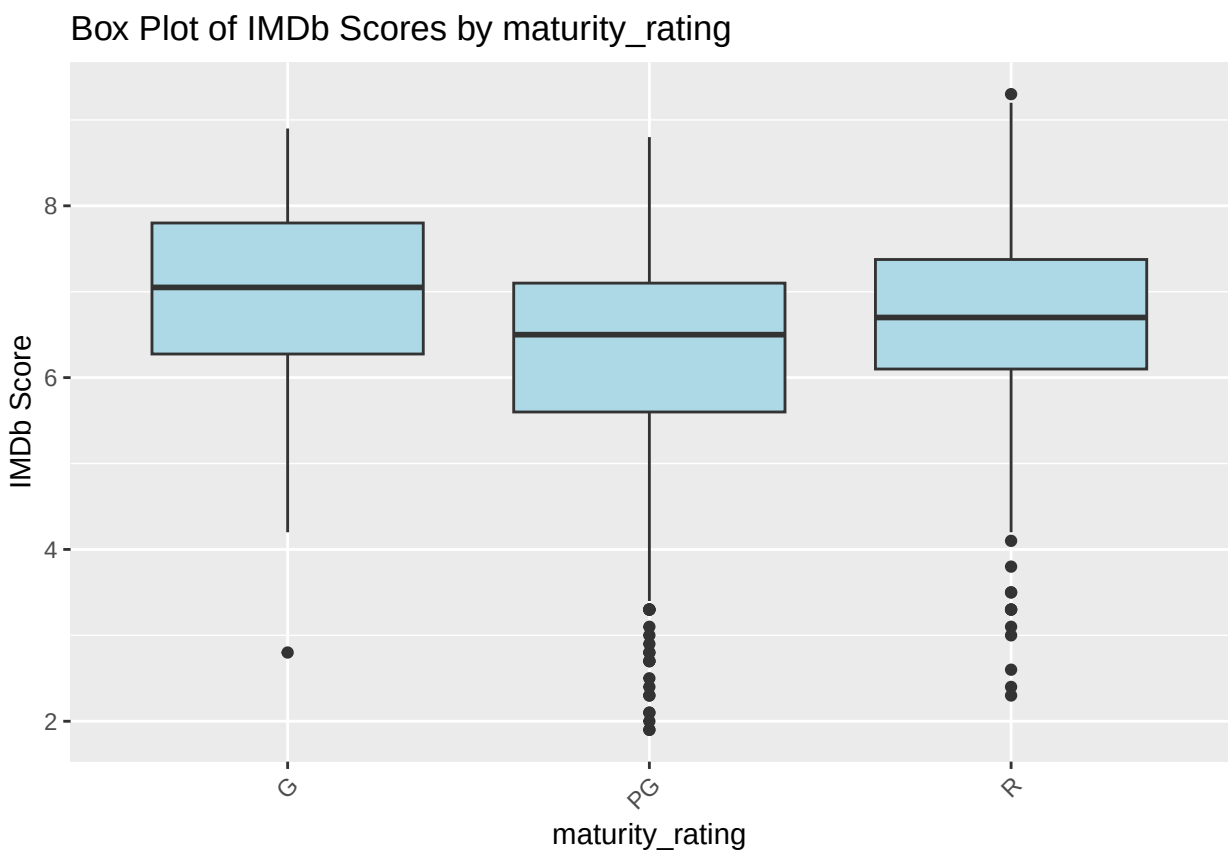
df$maturity_rating[df$maturity_rating %in% group_G] <- "G"
df$maturity_rating[df$maturity_rating %in% group_PG] <- "PG"
df$maturity_rating[df$maturity_rating %in% group_R] <- "R"

table(df$maturity_rating)
```

```
##
##    G   PG    R
##   60  840 1030
```

G and R are quite similar in terms of imdb_score.

```
ggplot(df, aes(x = maturity_rating, y = imdb_score)) +
  geom_boxplot(fill = "lightblue") +
  labs(title = "Box Plot of IMDb Scores by maturity_rating",
       x = "maturity_rating",
       y = "IMDb Score") +
  theme(axis.text.x = element_text(angle = 45, hjust = 1))
```



t-test

```
pairwise_results <- pairwise.t.test(df$imdb_score, df$maturity_rating, p.adjust.method = "bonferroni")
print(pairwise_results)
```

```
##
##  Pairwise comparisons using t tests with pooled SD
##
## data:  df$imdb_score and df$maturity_rating
##
##    G       PG
## PG 0.00019 -
## R  0.41722 0.0000000000012
##
## P value adjustment method: bonferroni
```

There is no significant difference in IMDb scores between the R and G ratings. However, combining them into a single group seems inappropriate, and there may be potential interaction effects with other predictors. So, we decide to keep all three levels.

```
table(df$country)
```

country

```
##
##          Aruba      Australia        Belgium         Brazil         Canada

##           Peru         Russia   South Africa    South Korea          Spain
##              1              1              5              2              7
##         Taiwan             UK            USA   West Germany
##              1            177           1555              1
```

We have 34 countries in the dataset, but some only have a single sample, making them quite rare. We approach it in two ways:

1. Reclassifying the countries by continent.
2. Grouping them into representative countries and creating an 'Other Countries' category for the rest.

When modeling, we'll evaluate which approach performs better.

Approach 1: Re-classify countries by continent

```
Africa <- c("South Africa", "Kenya", "Nigeria", "Egypt", "Ghana", "Morocco", "Uganda")
Asia <- c("China", "India", "Japan", "South Korea", "Indonesia", "Kyrgyzstan", "Russia", "Taiwan", "Hong
Europe <- c("Belgium", "Czech Republic", "Denmark", "France", "Georgia", "Germany", "Greece", "Hungary"
North_America <- c("USA", "Canada", "Mexico")
Central_South_America <- c("Aruba", "Brazil", "Colombia", "Peru")
Australia <- c("Australia", "New Zealand")
Other <- c("Official site")
```

```
df$continent <- 0

df$continent[df$country %in% Africa] <- "Africa"
df$continent[df$country %in% Asia] <- "Asia"
df$continent[df$country %in% Europe] <- "Europe"
df$continent[df$country %in% North_America] <- "North America"
df$continent[df$country %in% Central_South_America] <- "Central South America"
df$continent[df$country %in% Australia] <- "Australia"
df$continent[df$country %in% Other] <- "Other"

table(df$continent)
```

```
##
##                 Africa                   Asia              Australia
##                      5                     18                     28
## Central South America                 Europe          North America
##                      4                    280                   1594
##                  Other
##                      1
```

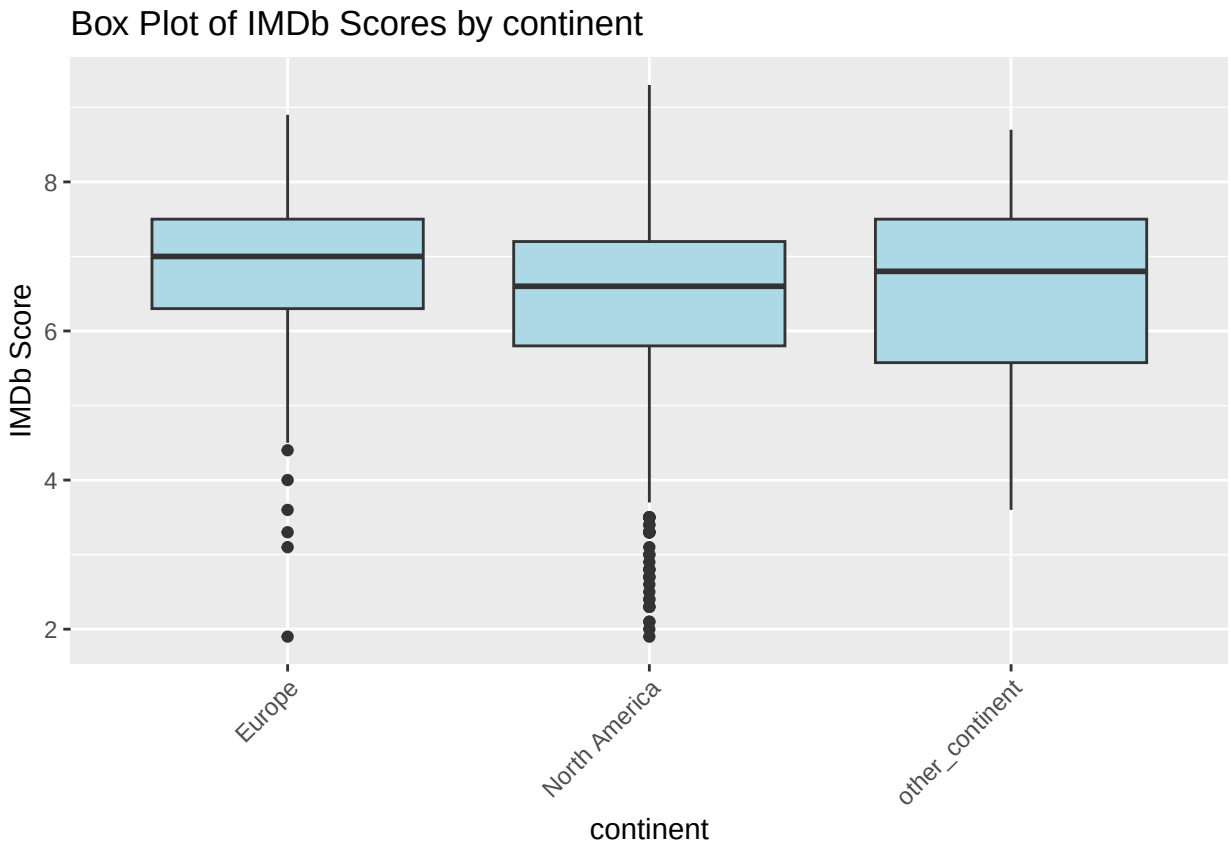
Since Africa, Asia, Australia, Central South America, Other each have fewer than 30 samples, which limits their statistical representation, we further consolidate these continents into "other_continents" category.

```
other_continent <- c("Africa", "Asia", "Australia", "Central South America", "Other")
df$continent[df$continent %in% other_continent] <- "other_continent"

table(df$continent)
```

```
##
##          Europe   North America other_continent
##             280            1594              56
```

```
ggplot(df, aes(x = continent, y = imdb_score)) +
  geom_boxplot(fill = "lightblue") +
  labs(title = "Box Plot of IMDb Scores by continent",
       x = "continent",
       y = "IMDb Score") +
  theme(axis.text.x = element_text(angle = 45, hjust = 1))
```



t-test

```
pairwise_results <- pairwise.t.test(df$imdb_score, df$continent, p.adjust.method = "bonferroni")
print(pairwise_results)
```

```
##
##  Pairwise comparisons using t tests with pooled SD
##
## data:  df$imdb_score and df$continent
##
##                 Europe     North America
## North America   0.00000015 -
## other_continent 0.38       1.00
##
## P value adjustment method: bonferroni
```

Although the t-test shows no significant difference in IMDb scores between 'other_continent' and Europe or between 'other_continent' and North America, keeping 'other_continent' as a separate category still provides additional granularity and may help capture nuanced interactions with other predictors. We'll see.

Approach 2: Re-classify countries by frequncy

```
over_30_countries <- c("Germany", "West Germany", "Canada", "France", "UK", "USA")
over_30_germany <- c("West Germany")

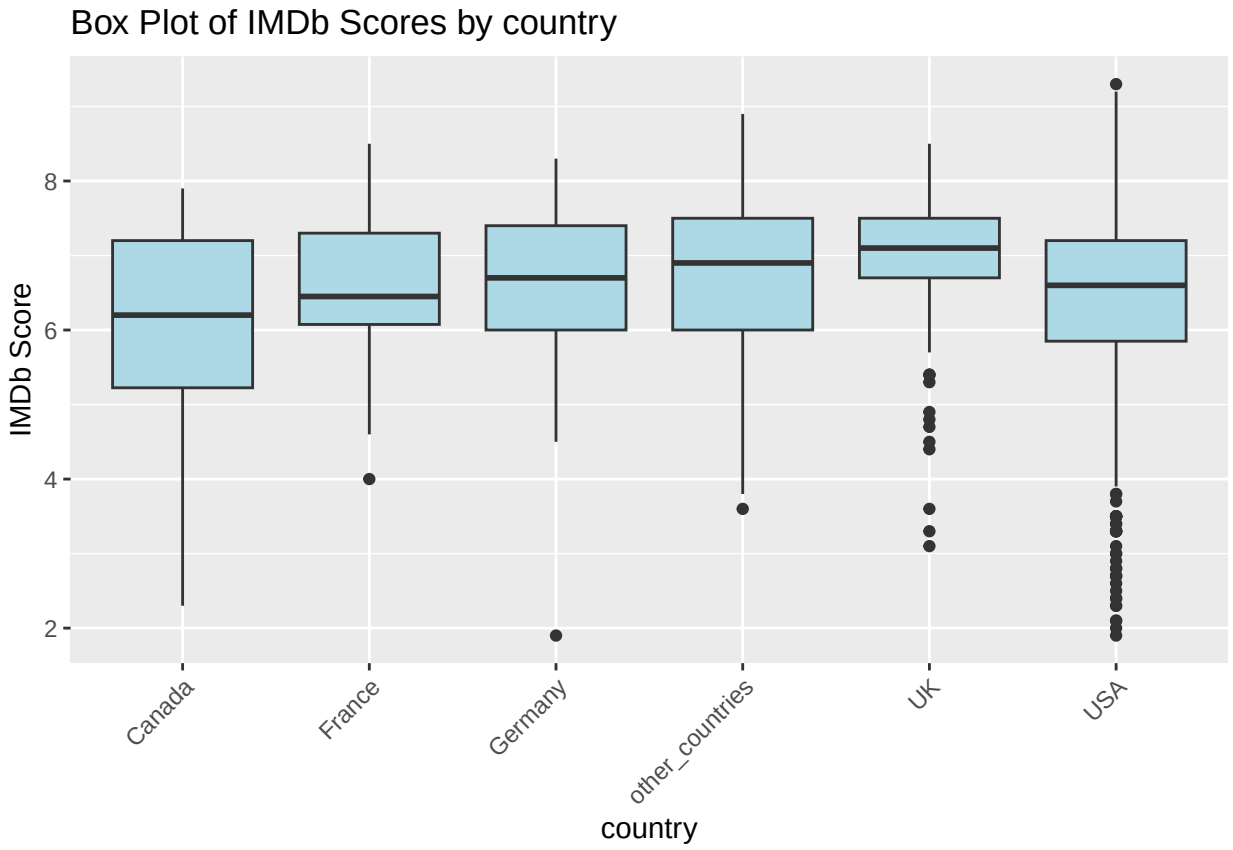
df$country[!(df$country %in% over_30_countries)] <- "other_countries"
df$country[df$country %in% over_30_germany] <- "Germany"

table(df$country)
```

```
##
##          Canada          France         Germany other_countries              UK
##              38              40              35              85             177
##             USA
##            1555
```

Box-plot

```
ggplot(df, aes(x = country, y = imdb_score)) +
  geom_boxplot(fill = "lightblue") +
  labs(title = "Box Plot of IMDb Scores by country",
       x = "country",
       y = "IMDb Score") +
  theme(axis.text.x = element_text(angle = 45, hjust = 1))
```



t-test

```
pairwise_results <- pairwise.t.test(df$imdb_score, df$country, p.adjust.method = "bonferroni")
print(pairwise_results)
```

```
##
##  Pairwise comparisons using t tests with pooled SD
##
## data:  df$imdb_score and df$country
##
##                Canada  France Germany other_countries UK
## France         0.293   -      -       -               -
## Germany        0.782   1.000  -       -               -
## other_countries 0.023  1.000  1.000   -               -
```

```
## UK              0.00002257 0.855  0.416   0.959           -
## USA             0.201      1.000  1.000   0.860           0.00000015
##
## P value adjustment method: bonferroni
```

Despite the lack of strong significance in most comparisons, keeping the 'other_countries' category allows for finer granularity and could help capture nuanced interactions with other predictors. Who knows what might happen when we run some non-linear or non-parametric models!!!

Personnel The way we approach personnel-related predictors is as follows:

Steps:

1. Identify the top 10 entries for each predictor
2. Create new dummy columns indicating whether a movie falls within the top 10 for each personnel predictor

Identify the top 10 entries for each predictor

```
personnel_cols <- c("director", "actor1", "actor2", "actor3", "cinematographer", "production_company",

top_10_list <- list()

for (col in personnel_cols) {
  top_10 <- head(sort(table(df[[col]]), decreasing = TRUE), 10)

  # Store the top 10 in the list with the column name as the key
  top_10_list[[col]] <- top_10

  cat("Top 10 for", col, ":\n")
  print(top_10)
  cat("-------------------------\n")

  sum_top_10 <- sum(top_10)
  cat("Sum of Top 10:", sum_top_10, "\n")
  cat("-------------------------\n")
}
```

```

```

Release timing Even though the upcoming movies we're predicting are all released in November, and the timing predictors might seem irrelevant, they could still be valuable. If historical data reveals significant trends or patterns associated with **specific days of the week**, **release periods within a month (early, mid, or late month)**, or whether **it's a weekday or weekend**, these predictors could help improve the model's performance.

bar chart (Distribution)

We can classify the day into three groups representing early, mid, and late parts of a month to see whether there's a trend.

```
# convert the chr to factor, so that the plot will present in order
df$release_month <- factor(df$release_month, levels = c("Jan", "Feb", "Mar", "Apr", "May", "Jun",
```

```
                                                    "Jul", "Aug", "Sep", "Oct", "Nov", "Dec"))

df$release_day_group <- cut(as.numeric(df$release_day),
                            breaks = c(0, 10, 20, 31),
                            labels = c("Early Month", "Mid Month", "Late Month"),
                            right = TRUE)

From the analysis above, it seems like time-related predictors are useless. The decreasing trend observed in the year dimension is likely due to sample size rather than an actual decline in IMDb scores. Also, no discernible pattern spotted, regardless of the time granularity analyzed.

Mon ~ Sun / Weekday or Weekend

One more thing we can take with them is to analyze whether the release day falls on a weekday / weekend, or on a specific day of the week, has any effect on the IMDb scores.

```
df$date <- as.Date(with(df, paste(release_year, release_month, release_day, sep = "-")), "%Y-%b-%d")

# Get the day of the week (1 = Sunday, 7 = Saturday)
df$day_of_week <- wday(df$date, label = TRUE)
df$weekday_or_weekend <- ifelse(df$day_of_week %in% c("Sat", "Sun"), "Weekend", "Weekday")

head(df[c("release_year", "release_month", "release_day", "day_of_week", "weekday_or_weekend")])
```

```

pairwise t-test

Since the movies we're going to predict are all being released in Oct or Nov, it makes more sense to focus on time-related predictors at a granularity of month or smaller. Given that the day unit is too small, we've decided to just focus on two groups: 'weekend / weekday,' and 'early / mid / late month.'

```
time_cols <- c("day_of_week", "weekday_or_weekend", "release_day_group")

for (col in time_cols) {

    pairwise_results <- pairwise.t.test(df$imdb_score, df[[col]], p.adjust.method = "bonferroni")
    print(pairwise_results)

}
```

```

##
## P value adjustment method: bonferroni
```

Although there is no significant difference in IMDb scores between levels within each group, this interpretation relies solely on linear perspectives. In a similar fashion to previous predictors, retaining these variables could still be valuable for capturing potential interactions with other predictors. Also, they can enhance visual analysis when exploring trend patterns.

Drop useless columns

```
drop_release_cols <- c("date", "release_year", "release_month", "release_day")
df[drop_release_cols] <- NULL

colnames(df)

EDA - numerical predictors Moving on to the numerical variables. Similar to the approach taken with categorical predictors, we conduct outlier detection, skewness, scaling and normalization, feature engineering, or data type conversion.

Histograms

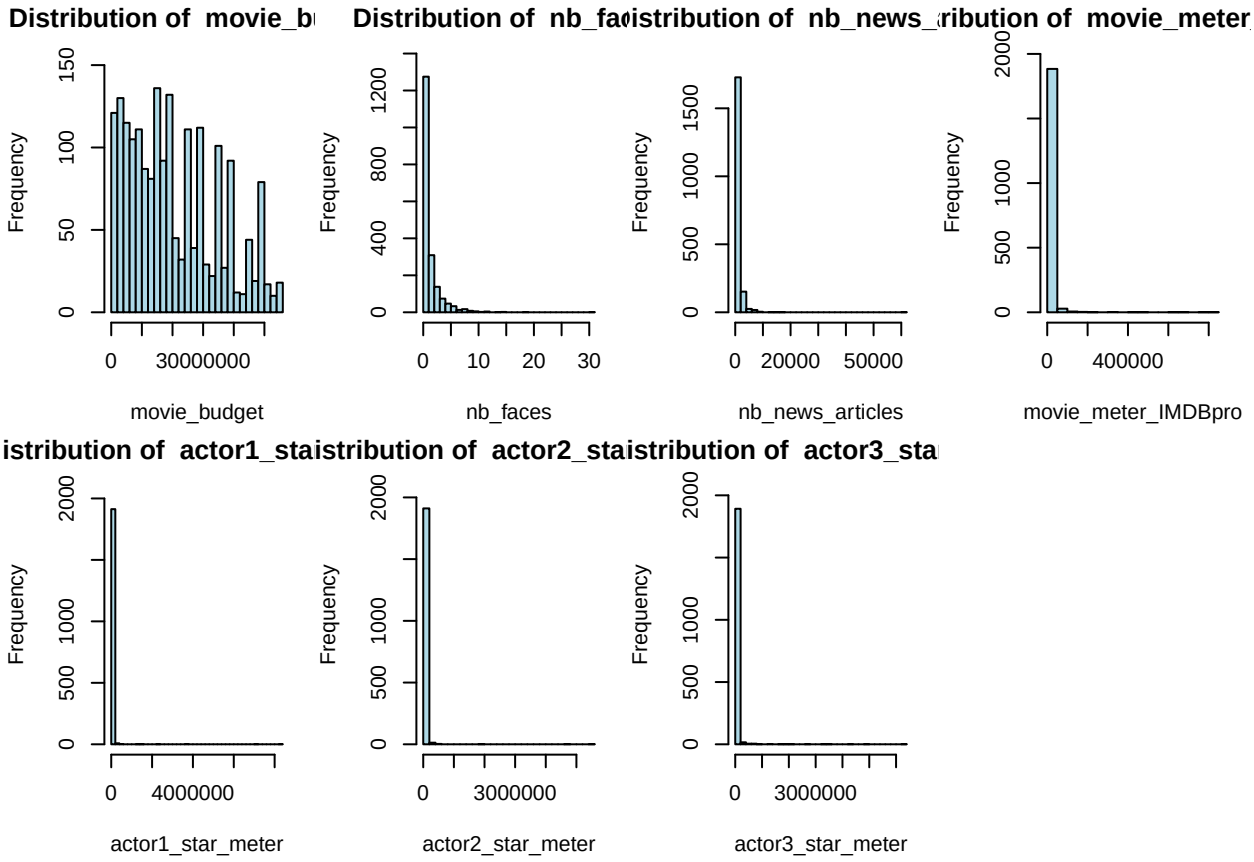
```
num_cols <- c("movie_budget", "nb_faces", "nb_news_articles", "movie_meter_IMDBpro", "actor1_star_meter

options(scipen = 999)
```

```r
par(mfrow = c(2, 4), mar = c(4, 4, 2, 1))

for (col in num_cols) {
  hist(df[[col]],
       main = paste("Distribution of ", col),
       xlab = col,
       col = "lightblue",
       breaks = 30,
       ylim = c(0, max(table(cut(df[[col]], breaks = 30)), na.rm = TRUE) * 1.1) # Adjust ylim to add so
  )
}

par(mfrow = c(1, 1), mar = c(5, 4, 4, 2) + 0.1)
```



Box Plots

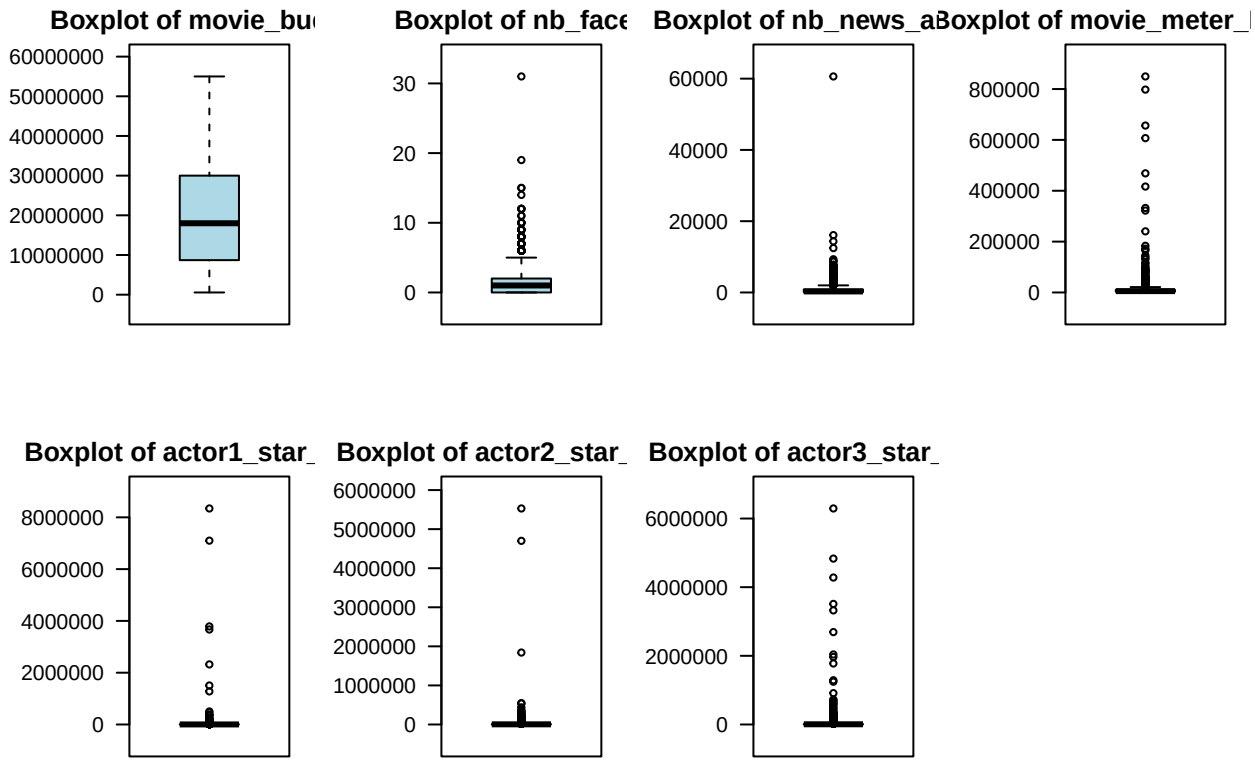
```r
par(mfrow = c(2, 4), mar = c(4, 5, 2, 1), oma = c(0, 0, 0, 0))

for (col in num_cols) {

  boxplot(df[[col]],
          main = paste("Boxplot of", col),
          col = "lightblue",
          las = 2,
          ylim = range(df[[col]], na.rm = TRUE) + c(-1, 1) * diff(range(df[[col]], na.rm = TRUE)) * 0.1
          )
```

```
}

par(mfrow = c(1, 1), mar = c(5, 4, 4, 2) + 0.1)
```



Except for movie_budget, all predictors show a significant right skew due to outliers. We thus remove those fall outside of 3 IQR from the dataset.

```
cleaned_df <- df

par(mfrow = c(2, 4), mar = c(4, 5, 2, 1), oma = c(0, 0, 0, 0))

for (col in num_cols) {

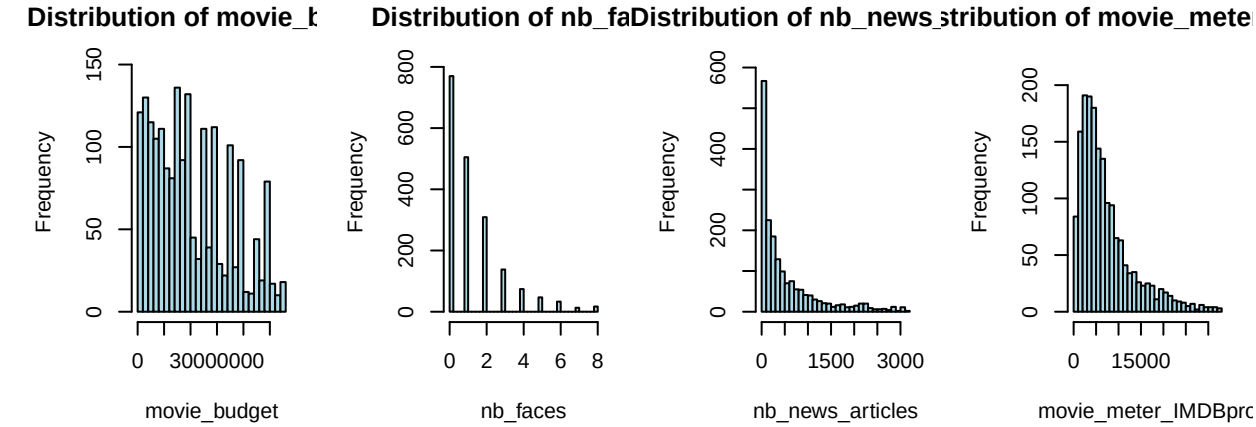
  Q1 <- quantile(cleaned_df[[col]], 0.25, na.rm = TRUE)
  Q3 <- quantile(cleaned_df[[col]], 0.75, na.rm = TRUE)
  IQR <- Q3 - Q1

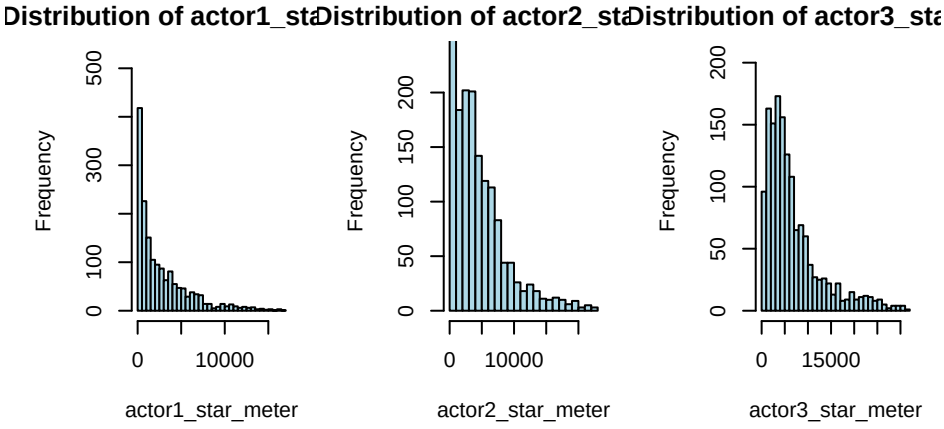
  lower_bound <- Q1 - 3 * IQR
  upper_bound <- Q3 + 3 * IQR

  cleaned_df <- cleaned_df[cleaned_df[[col]] >= lower_bound & cleaned_df[[col]] <= upper_bound, ]

  hist(cleaned_df[[col]],
       main = paste("Distribution of", col),
       xlab = col,
       col = "lightblue",
       breaks = 30,
       ylim = c(0, max(table(cut(cleaned_df[[col]], breaks = 30)), na.rm = TRUE) * 1.1)
      )
}
```

```
par(mfrow = c(1, 1), mar = c(5, 4, 4, 2) + 0.1)
```





```
print(dim(cleaned_df)) #  dropped rows = 479, drop rate = 25%
```

```
## [1] 1451   43
```

log transformation

Since after removing 3 IQR, predictor are still right skewed, we decide to use log transformation to reduce skewness.

```
for (col in num_cols) {
  # use log (x + 1) since there're 0 in some predictors
  cleaned_df[[paste0(col, "_log")]] <- log(cleaned_df[[col]] + 1)
  }
```

histogram

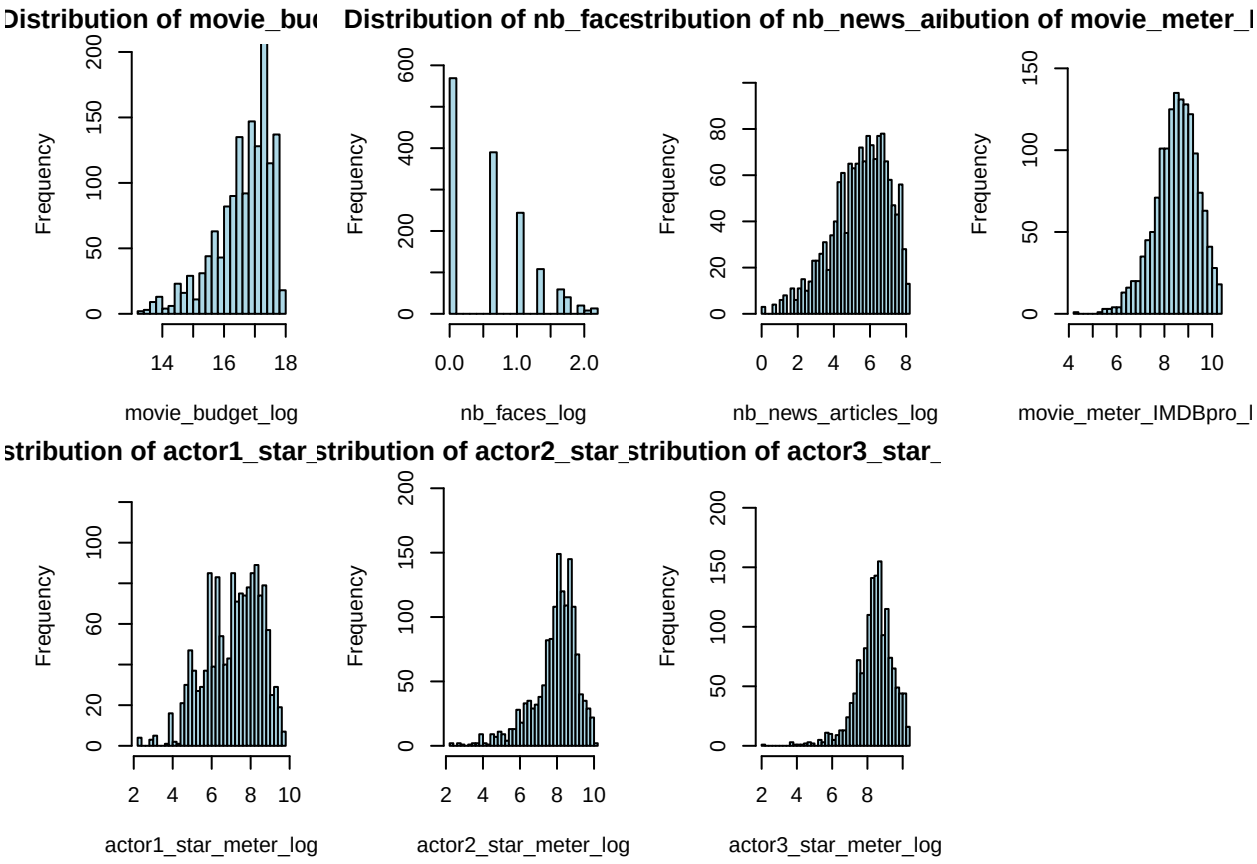
```
log_num_cols <- paste0(num_cols, "_log")

par(mfrow = c(2, 4), mar = c(4, 5, 2, 1), oma = c(0, 0, 0, 0))

for (col in log_num_cols) {
 hist(cleaned_df[[col]],
         main = paste("Distribution of", col),
         xlab = col,
         col = "lightblue",
         breaks = 30,
```

```
        ylim = c(0, max(table(cut(cleaned_df[[col]], breaks = 30)), na.rm = TRUE) * 1.1) # Adjust ylim
      )
  }

par(mfrow = c(1, 1), mar = c(5, 4, 4, 2) + 0.1)
```



While distributions of some predictors are left skewed, but they appear to be relatively symmetric than extremely skewed originally after transformation.

Note:

- For the actor star meter variables, since they all show similar patterns, we might consider creating a single feature that combines this information to reduce dimensionality (could be like taking the average log star meter of the top 3 actors)
- For those left-skewed distributions after log transformation, we might consider:
  a) Using a different transformation such as square root, cube root, Box-Cox transformation. . . .
  b) Binning the data into categories.
  c) Using the raw data if our modeling technique doesn't follow normality (e.g., tree-based methods. . .)

Scatter Plots & Correlation matrix

```
options(scipen=999)

ggpairs(cleaned_df[c("imdb_score", num_cols)],
        upper = list(continuous = wrap("cor", size = 4)),
        lower = list(continuous = wrap("points", alpha = 0.6)),
        diag = list(continuous = "barDiag"),
```

```
        progress = FALSE, message = FALSE, warnings = FALSE)
```

```
## Warning in warn_if_args_exist(list(...)): Extra arguments: 'message',

## `stat_bin()` using `bins = 30`. Pick better value with `binwidth`.
## `stat_bin()` using `bins = 30`. Pick better value with `binwidth`.
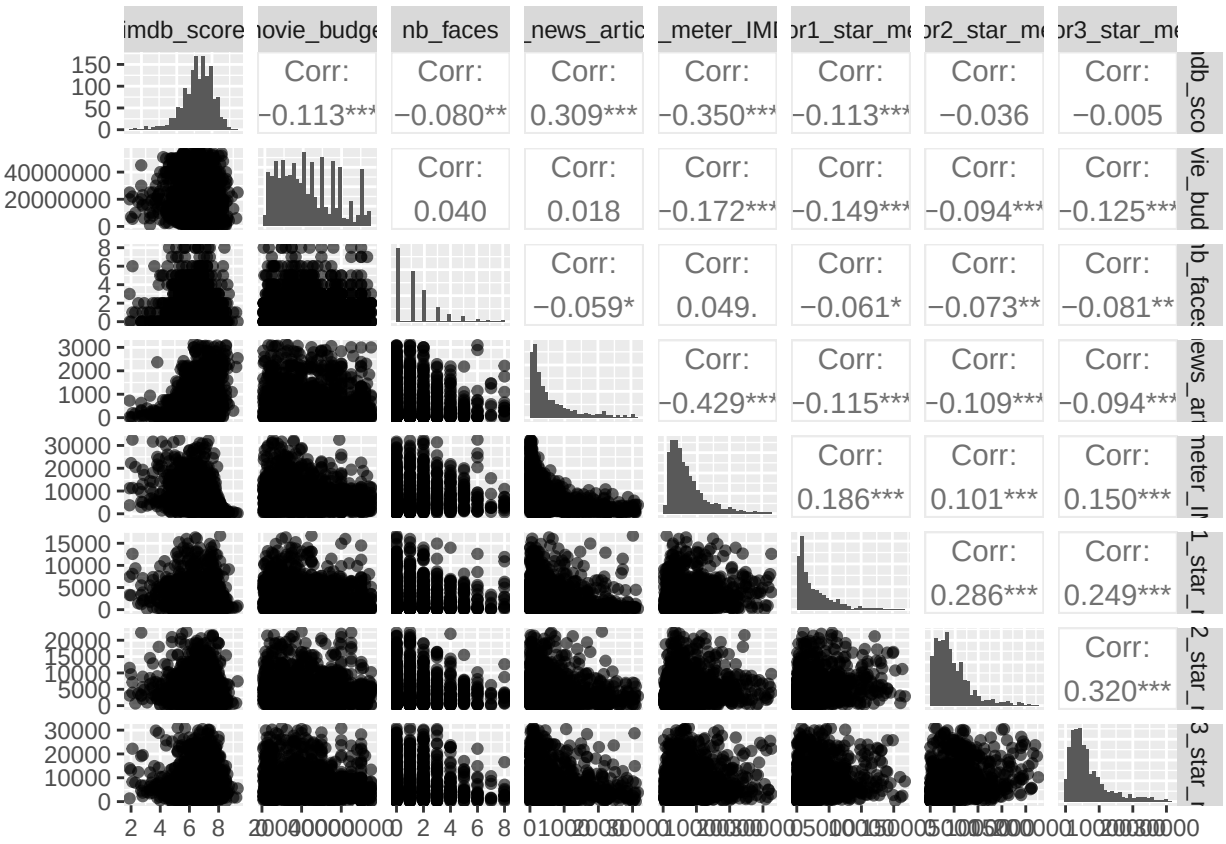
```



Except for the moderate negative correlation between the number of news articles and IMDbPro movie meter rankings, suggesting that movies with more media coverage tend to have better (lower) IMDbPro rankings, many of the other correlations are relatively weak.

The relationships between the target are not straightforward, indicate potential non-linear : movie_meter_IMDBpro, actor star meters shows some curvature;

We could further explore potential complex interactions between variables through cross-analysis.

Trending Analysis Target variable

```
plot_list <- list()
```

```r
for (time in time_cols) {

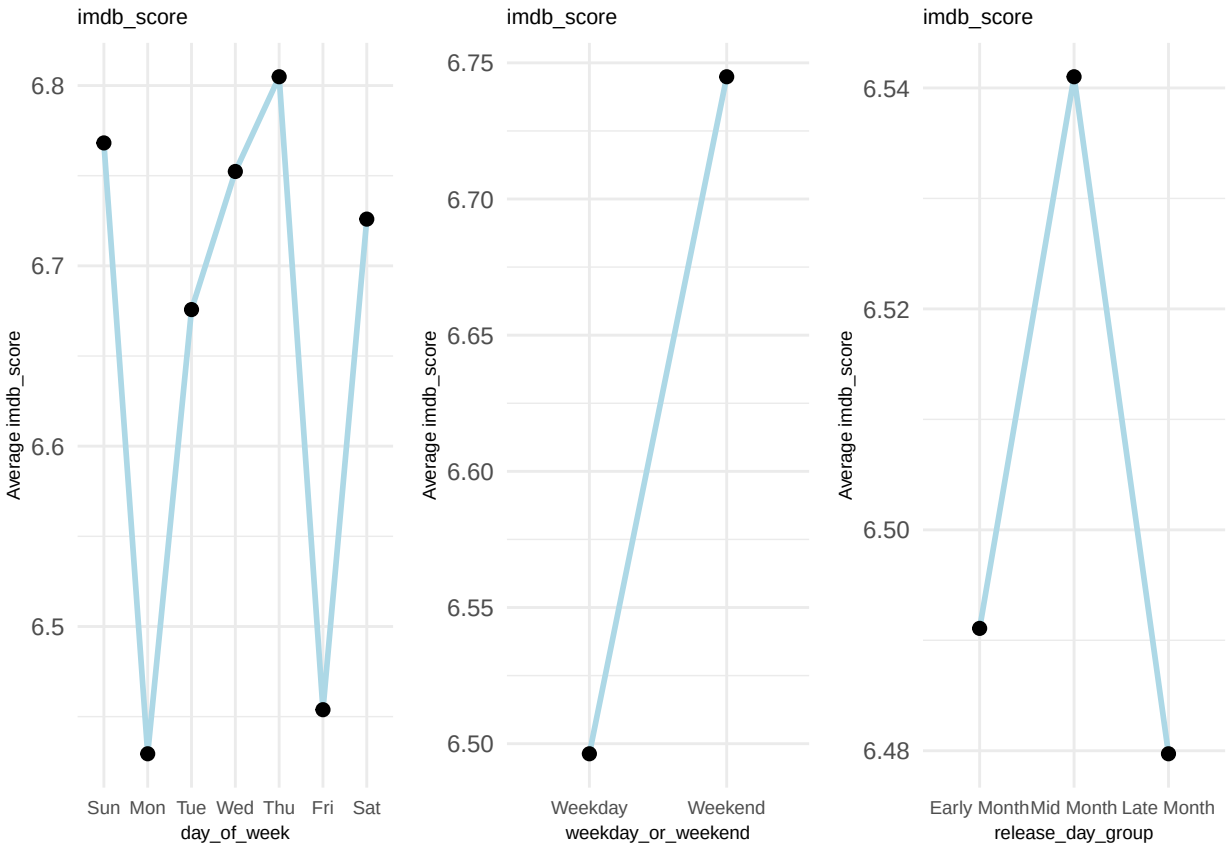
  df_summary <- cleaned_df %>%
    group_by(.data[[time]]) %>%
    summarise(mean_value = mean(.data[["imdb_score"]], na.rm = TRUE))

  p <- ggplot(df_summary, aes_string(x = time, y = "mean_value", group = 1)) +
    geom_line(color = "lightblue", size = 1) +
    geom_point(color = "black", size = 2) +
    labs(title = "imdb_score",
         x = time,
         y = "Average imdb_score") +
    theme_minimal() +
    theme(
      plot.title = element_text(size = 8),
      axis.title.y = element_text(size = 7),
      axis.title.x = element_text(size = 7),
      axis.text.x = element_text(size = 7)
    )

  plot_list <- c(plot_list, list(p))
}
```

```
## Warning: Using `size` aesthetic for lines was deprecated in ggplot2 3.4.0.
## i Please use `linewidth` instead.
## This warning is displayed once every 8 hours.
## Call `lifecycle::last_lifecycle_warnings()` to see where this warning was
## generated.
```

```r
grid.arrange(grobs = plot_list, ncol = 3, nrow = 1)
```



Movies released on weekends or mid-month tend to have higher rating scores, but their effect seems moderate.

Numerical predictors

```
plot_list <- list()

for (col in num_cols) {

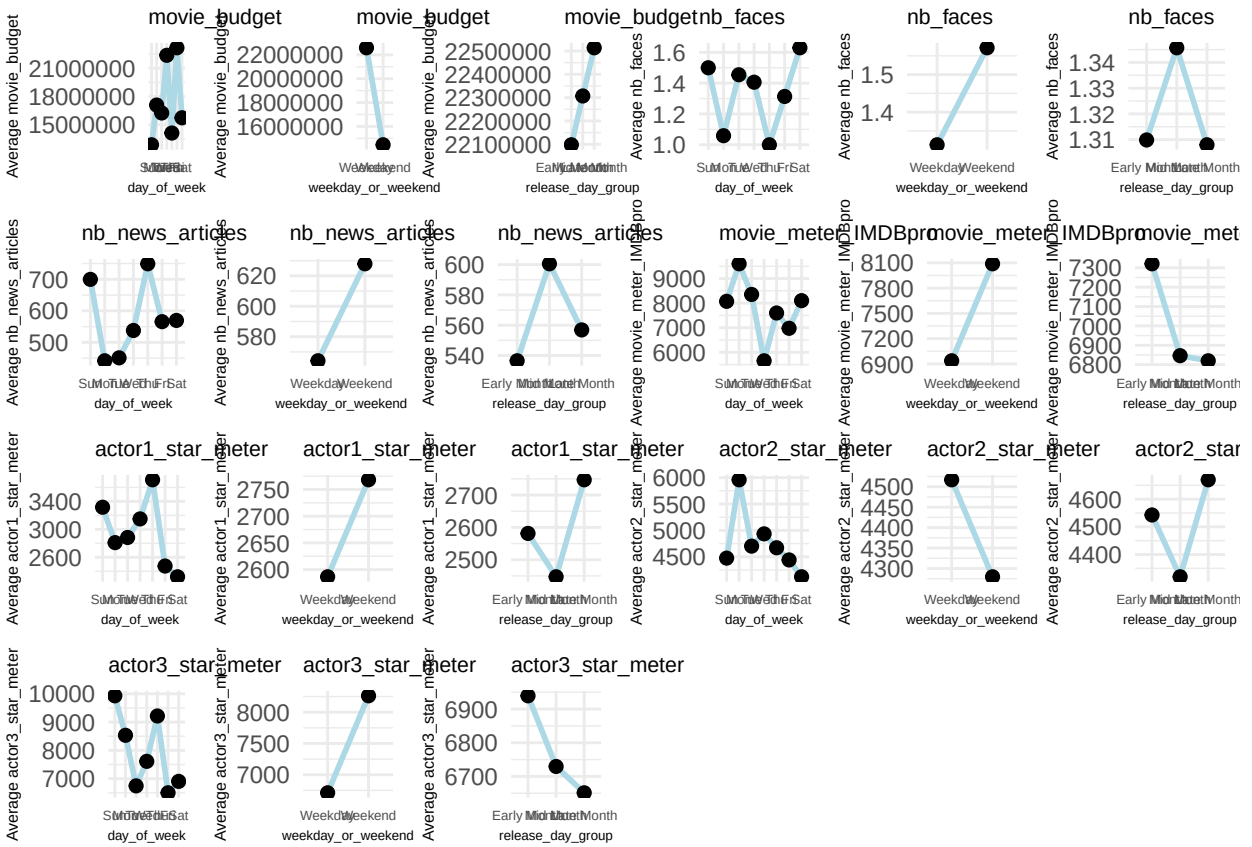
  for (time in time_cols) {

    df_summary <- cleaned_df %>%
      group_by(.data[[time]]) %>%
      summarise(mean_value = mean(.data[[col]], na.rm = TRUE))

    p <- ggplot(df_summary, aes_string(x = time, y = "mean_value", group = 1)) +
      geom_line(color = "lightblue", size = 1) +
      geom_point(color = "black", size = 2) +
      labs(title = col,
           x = time,
           y = paste("Average", col)) +
      theme_minimal() +
      theme(
        plot.title = element_text(size = 8),
        axis.title.y = element_text(size = 6),
        axis.title.x = element_text(size = 5),
        axis.text.x = element_text(size = 5)
      )
```

```
    plot_list <- c(plot_list, list(p))
  }
}

grid.arrange(grobs = plot_list, ncol = 6, nrow = 4)
```



From the trend plots, it indicates that movies released during different timeframes may have varying effects on the predictors.

Answer those business questions

Q1. What predictors have high correlation with IMDb scores? Is there any possible collinearity between predictors?

correlation with target variables

```
options(contrasts = c("contr.treatment", "contr.treatment"))  # Use simple dummy coding for unordered f

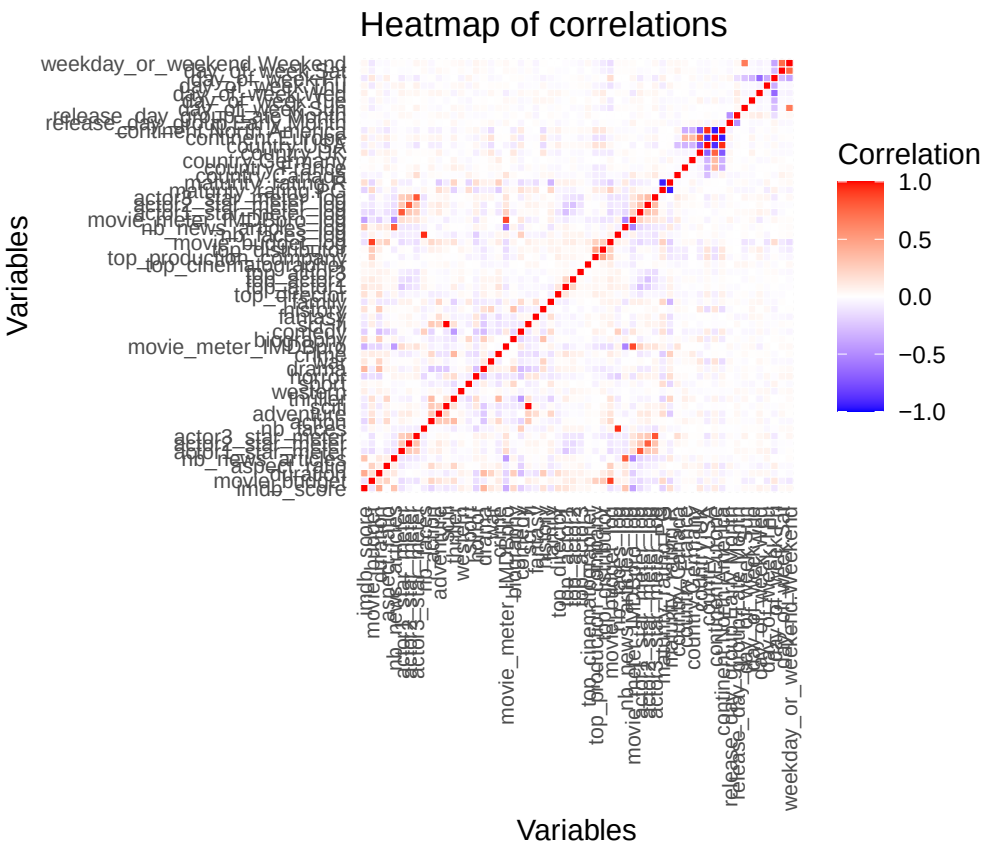
  coord_fixed() +  # Fix the aspect ratio
  labs(title = "Heatmap of correlations", x = "Variables", y = "Variables")
```



Some predictors are kept in the dataset for performance testing later, so their high correlation is not a primary focus (e.g., continent and country, day of the week vs. weekday/weekend, log vs. non-log versions).

However, several important correlations are worth noting within specific predictor groups

1. Significant Correlations Within Predictor Levels

There are notable correlations between related variables such as actor star meters, country-specific variables, day-of-week variables, and time-of-month variables (late vs. early month). Also, there is a perfect negative correlation between maturity ratings (R vs. PG), indicating these categories are mutually exclusive, making it necessary to include only one to avoid multicollinearity.

2. IMDbPro vs. Number of News Articles

- Positive Correlation

The number of news articles and IMDbPro movie meter (log version) show a moderate-to-high positive correlation, indicating that movies with more media coverage tend to perform better in IMDbPro rankings. Since both metrics capture elements of movie visibility and popularity, they may exhibit collinearity. Testing their individual impact on the model will help identify which is more predictive.

- Negative Correlation

There's also a moderate-to-strong negative correlation between the number of news articles and IMDbPro (log). This suggests that while increased media attention may draw more visibility, it doesn't always translate into higher IMDbPro rankings, reflecting that more attention doesn't necessarily equate to better audience perceptions or ratings.

correlation with target variables

```
cor_with_target <- correlation_matrix[, "imdb_score"]

cor_with_target_sorted <- sort(cor_with_target, decreasing = TRUE)

cor_with_target_sorted
```

```

```

Positive correlation 1. Strong (> 0.3): duration, drama, number of news articles 2. Moderate (> 0.15): biography, maturity_rating.R, top_director, history, history, war, country.UK

Negative correlation 1. Strong (< -0.3): movie_meter_IMDBpro, No matter it's non-log or log version 2. Moderate (< -0.15): comedy, horror, maturity_rating.PG

Many other predictors show moderate to weak correlations, suggesting they may not have a strong, direct impact on IMDb scores individually. However, these weaker predictors could still contribute valuable insights through interactions or combinations with other features in the model, or in non-linear models.

Duration, drama, and number of news articles are the strongest positive influences, while the movie meter and certain genres or maturity ratings show the strongest negative effects. These insights suggest that they are likely to play a crucial role in the linear predictive model.

Q2. Does the release timing (day of the week, weekday or weekend, part of the month) affect IMDb scores?

Movies released on weekends or mid-month tend to have higher rating scores, but their effect seems moderate.

Q3. How does the combination of multiple genres in a movie affect its IMDb score?

network graph

```
genres_retained <- c("action", "adventure", "scifi", "thriller", "western",
                     "sport", "horror", "drama", "war", "crime", "biography",
```

```
                    "comedy", "fantasy", "history", "family", "other_genre")

high_rated_movies <- cleaned_df %>% filter(imdb_score >= 7.3) # 3rd Qu = 7.3

genre_matrix <- high_rated_movies %>% select(all_of(genres_retained))

# co-occurrence matrix calculation
co_occurrence_matrix <- as.matrix(t(genre_matrix)) %*% as.matrix(genre_matrix)

co_occurrence_df <- melt(co_occurrence_matrix) # need to convert to a dataframe
colnames(co_occurrence_df) <- c("Genre1", "Genre2", "Count")

# remove 0 and self-pairings
co_occurrence_df <- co_occurrence_df %>% filter(Count > 0 & Genre1 != Genre2)

graph <- graph_from_data_frame(co_occurrence_df, directed = FALSE)

ggraph(graph, layout = "fr") +
  geom_edge_link(aes(edge_width = Count), edge_colour = "lightblue") +
  geom_node_point(size = 5, color = "darkblue") +
  geom_node_text(aes(label = name), vjust = 1, hjust = 1, size = 4) +
  theme_void() +
  labs(title = "Co-occurrence network of genres in high rated movies")
```

```
## Warning: The `trans` argument of `continuous_scale()` is deprecated as of ggplot2 3.5.0.
## i Please use the `transform` argument instead.

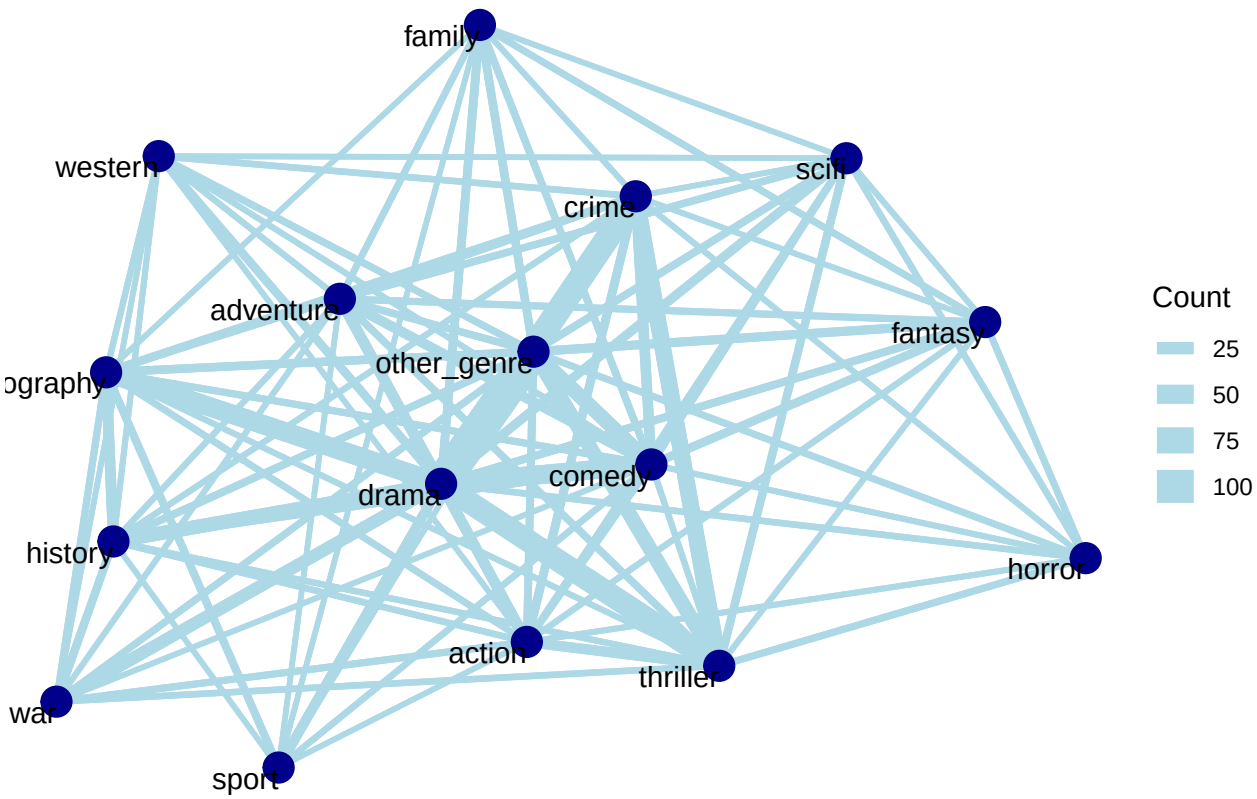
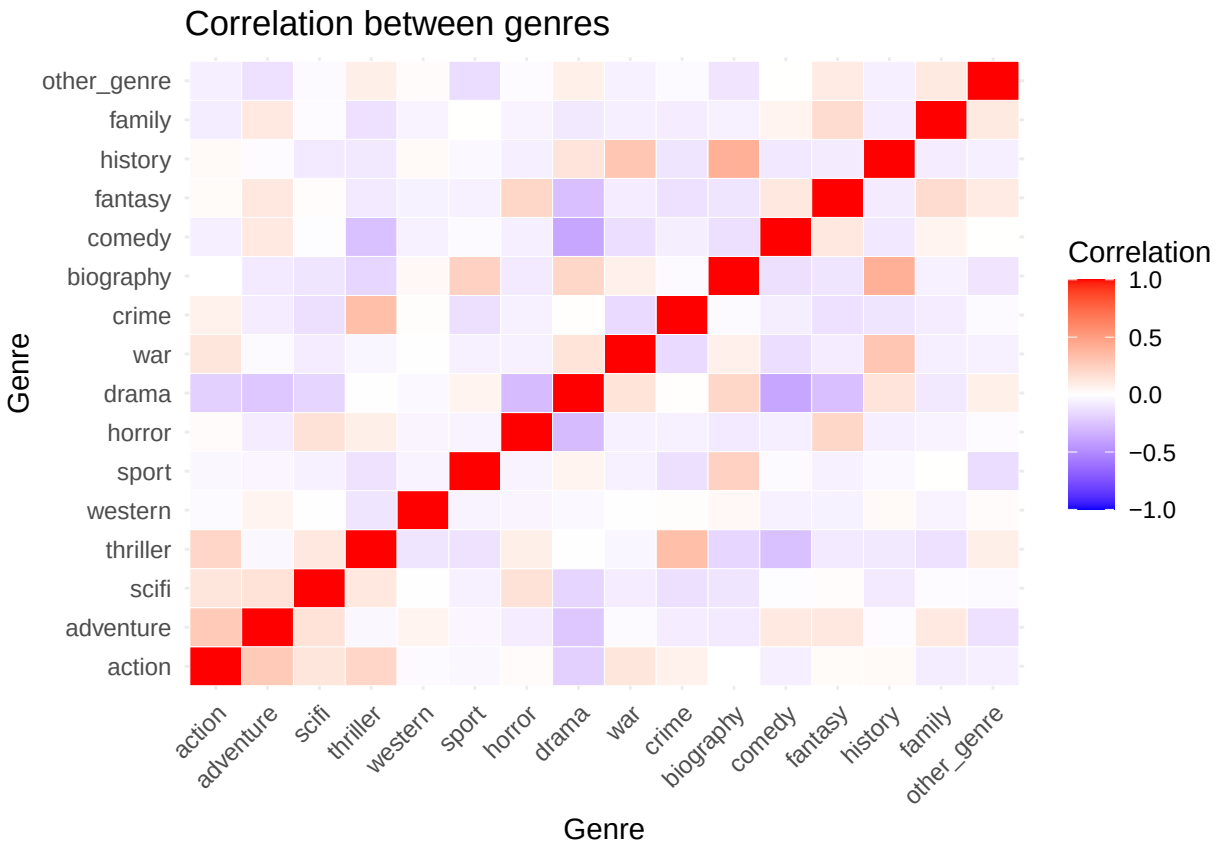
```



correlation heatmap

```
genre_corr_matrix <- cor(genre_matrix)

ggplot(melt(genre_corr_matrix), aes(x = Var1, y = Var2, fill = value)) +
  geom_tile(color = "white") +
  scale_fill_gradient2(low = "blue", high = "red", mid = "white", midpoint = 0, limit = c(-1, 1), space
  theme_minimal() +
  theme(axis.text.x = element_text(angle = 45, vjust = 1, hjust=1)) +
  labs(title = "Correlation between genres",
       x = "Genre",
       y = "Genre")
```



Some types of genres often co-occurring in high-rated movies. This suggests that introducing interaction terms for strongly correlated genre pairs could potentially be valuable for the model. (Action-Adventure, Action-Sci-Fi, Adventure-Sci-Fi, History-Biography, War-Biography, Thriller-Crime, Thriller-Action)

(*** other potential approach: add athother feature "genre diversity" by counting the number of genres per movie)

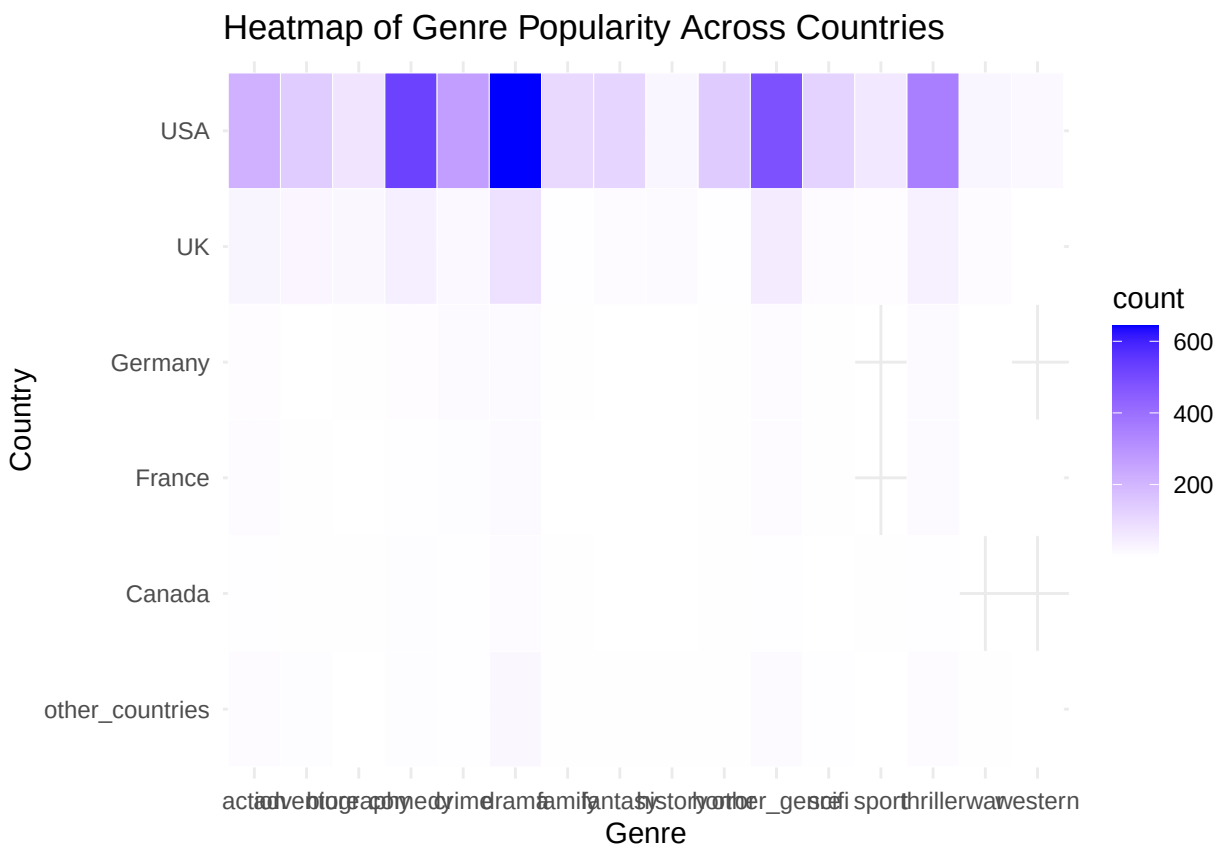
Q4. How does genre popularity differ across regions?

country

```
df_genres <- pivot_longer(cleaned_df, cols = all_of(genres_retained), names_to = "genre", values_to = "g
df_genres <- df_genres[df_genres$genre_indicator == 1, ]

genre_country_summary <- df_genres %>%
  group_by(country, genre) %>%
  summarise(count = n(), .groups = 'drop')

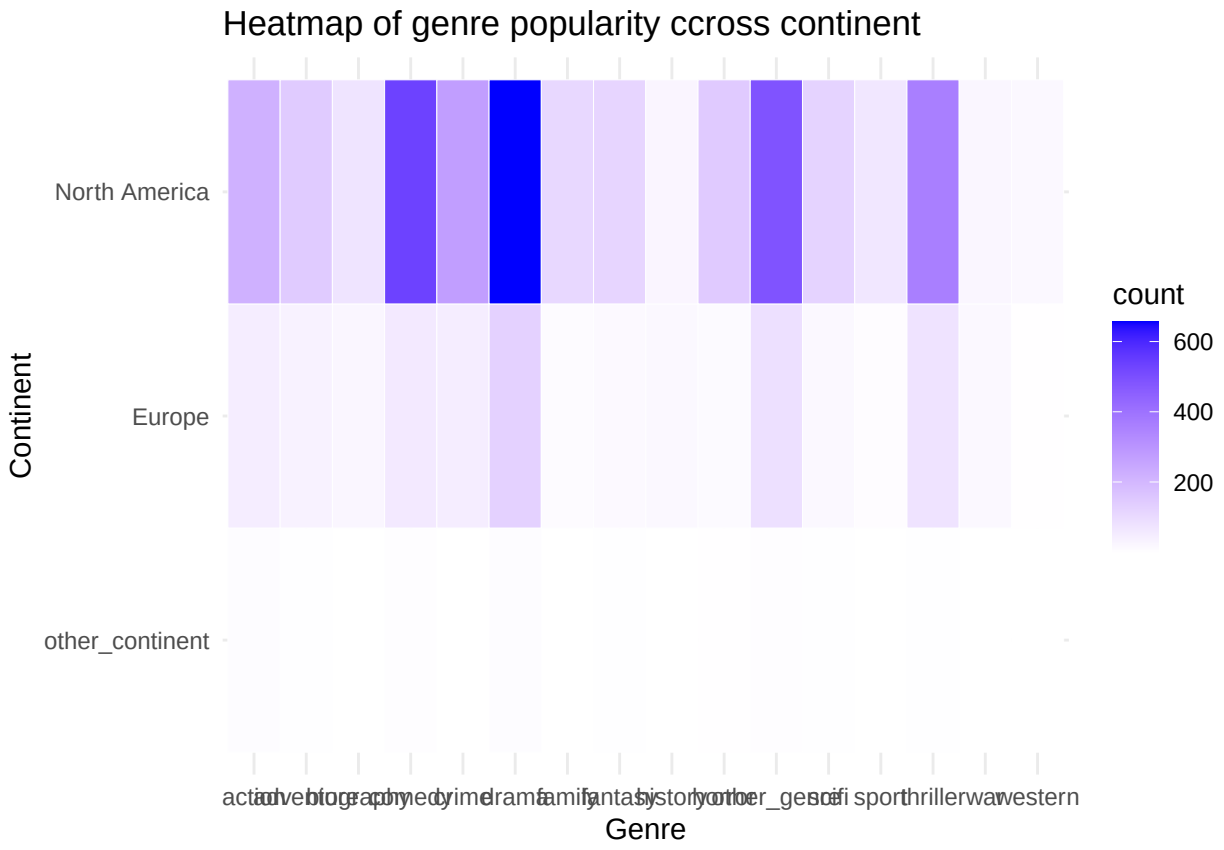
ggplot(genre_country_summary, aes(x = genre, y = country, fill = count)) +
  geom_tile(color = "white") +
  scale_fill_gradient(low = "white", high = "blue") +
  theme_minimal() +
  labs(title = "Heatmap of Genre Popularity Across Countries", x = "Genre", y = "Country")
```



continent

```
genre_continent_summary <- df_genres %>%
  group_by(continent, genre) %>%
  summarise(count = n(), .groups = 'drop')

ggplot(genre_continent_summary, aes(x = genre, y = continent, fill = count)) +
  geom_tile(color = "white") +
  scale_fill_gradient(low = "white", high = "blue") +
  theme_minimal() +
  labs(title = "Heatmap of genre popularity ccross continent", x = "Genre", y = "Continent")
```

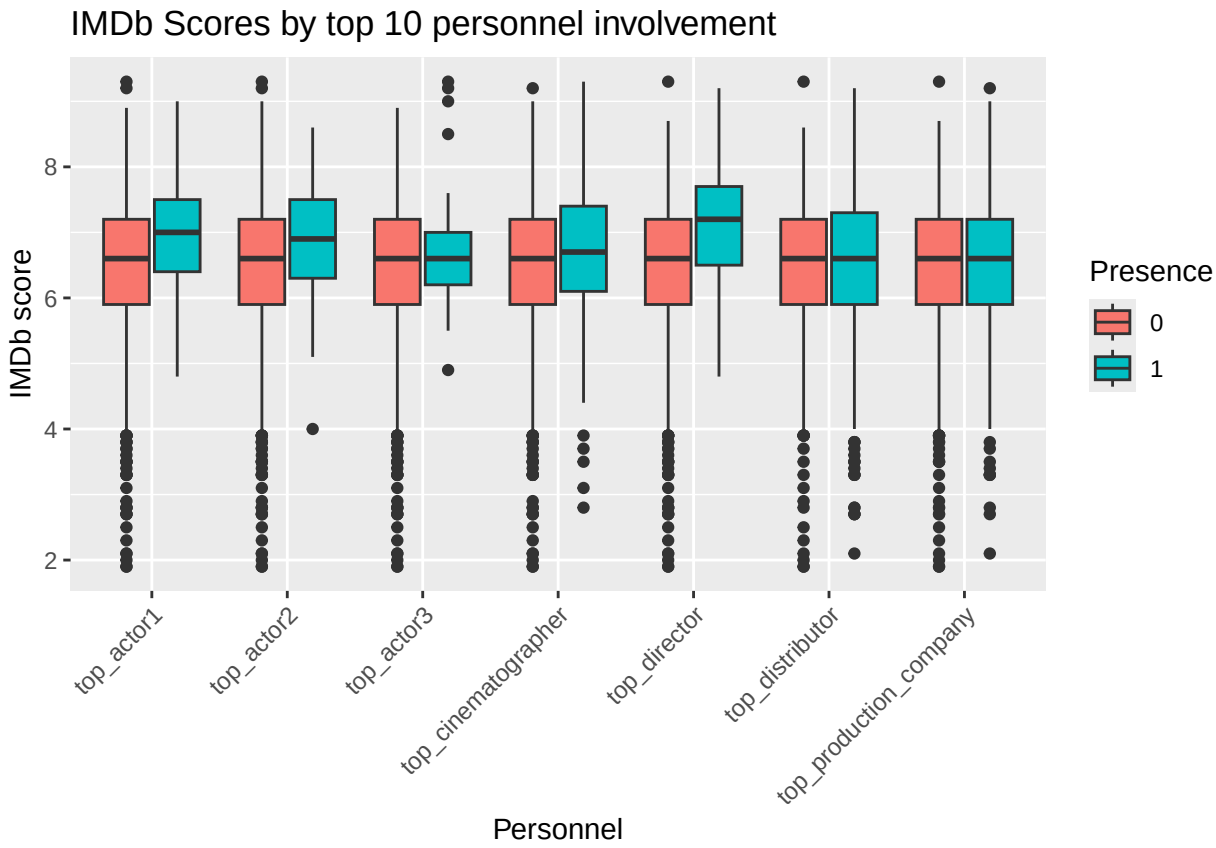


Due to the impact of sample size, the findings from the heatmaps are likely to be unreliable. To handle class imbalance, we might consider techniques like weighted sampling or stratification to ensure that the influence of different regions is properly balanced in the model.

Q5. How does the presence of top 10 personnel impact IMDb scores?

```
imdb_scores_by_personnel <- df_dummies %>%
  pivot_longer(cols = starts_with("top_"), names_to = "Personnel", values_to = "Presence")

ggplot(imdb_scores_by_personnel, aes(x = Personnel, y = imdb_score, fill = factor(Presence))) +
  geom_boxplot() +
  labs(title = "IMDb Scores by top 10 personnel involvement",
       x = "Personnel",
       y = "IMDb score",
       fill = "Presence") +
  theme(axis.text.x = element_text(angle = 45, hjust = 1))
```



The involvement of top 10 personnel, particularly directors and lead actors, generally correlates with higher IMDb scores. This indicates that including top personnel as features might contribute to predictive model, supporting our approach to feature engineering for personnel-related variables.

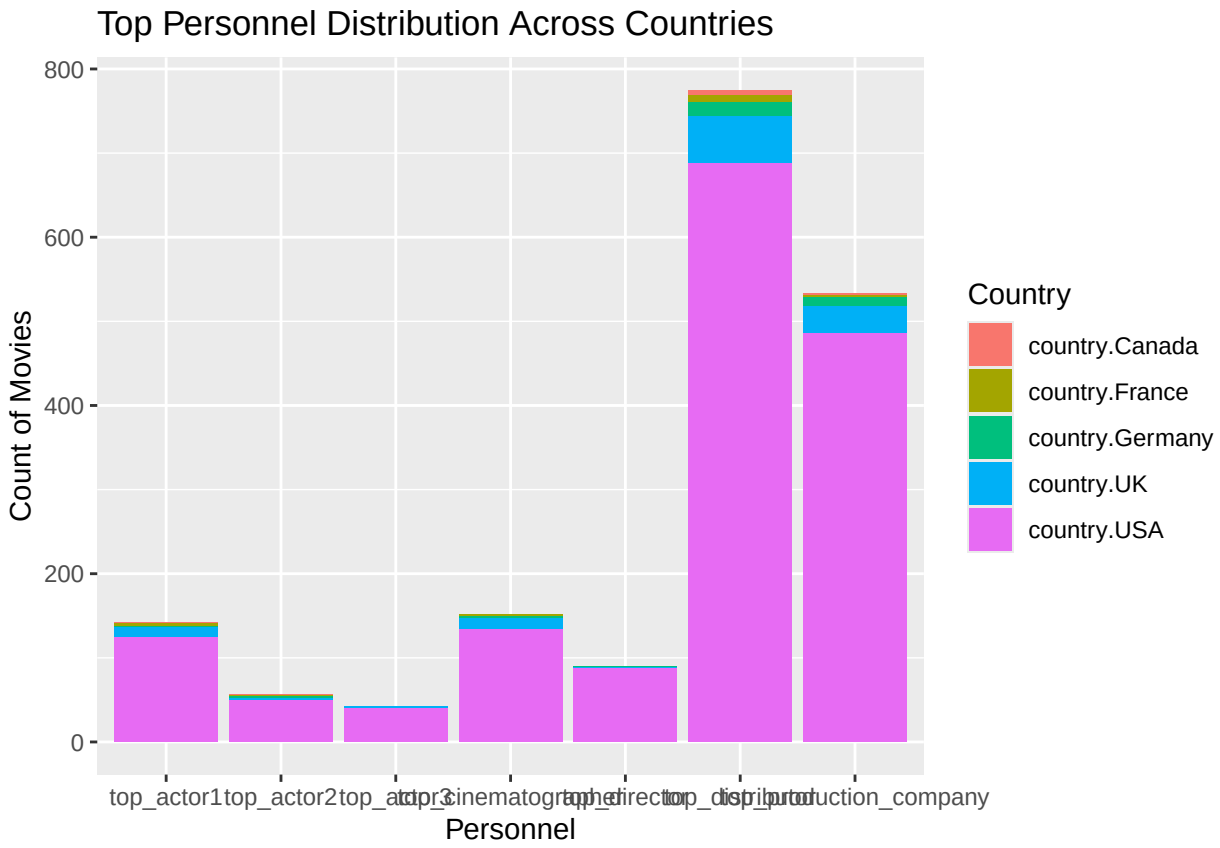
Q6. Look into movies associated with the top 10 personnel for each predictor. Do different personnel associate with certain countries? What types of movie genres tend to have the highest average IMDb scores among these top personnel?

```
country_by_personnel <- df_dummies %>%
  pivot_longer(cols = starts_with("top_"), names_to = "Personnel", values_to = "Presence") %>%
  filter(Presence == 1) %>%
  group_by(Personnel) %>%
  summarise(across(starts_with("country"), sum))

country_by_personnel_melted <- melt(country_by_personnel)
```

```
## Using Personnel as id variables
```

```
ggplot(country_by_personnel_melted, aes(x = Personnel, y = value, fill = variable)) +
  geom_bar(stat = "identity", position = "stack") +
  labs(title = "Top Personnel Distribution Across Countries", x = "Personnel", y = "Count of Movies", f
```



```
top_personnels <- c("top_director", "top_actor1", "top_actor2", "top_actor3", "top_cinematographer", "to

plot_list <- list()

for (personnel in top_personnels) {
  df_personnel <- cleaned_df %>% filter(!!sym(personnel) == 1)

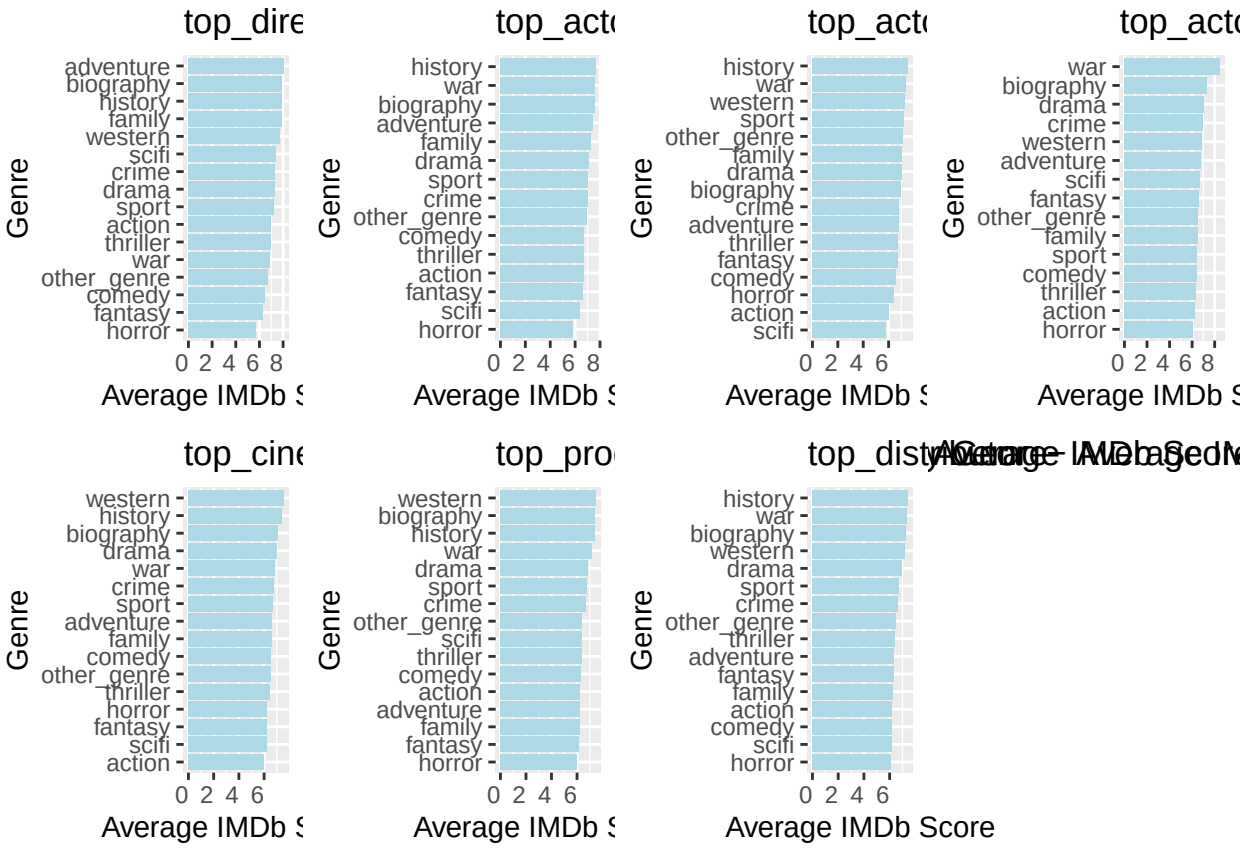
  df_long <- df_personnel %>%
    pivot_longer(cols = all_of(genres_retained), names_to = "genre", values_to = "genre_indicator") %>%
    filter(genre_indicator == 1)

  genre_avg_scores <- df_long %>%
    group_by(genre) %>%
    summarise(avg_score = mean(imdb_score, na.rm = TRUE), .groups = 'drop') %>%
    arrange(desc(avg_score))  # Sort by average score in descending order

  p <- ggplot(genre_avg_scores, aes(x = reorder(genre, avg_score), y = avg_score)) +
    geom_bar(stat = "identity", fill = "lightblue") +
    labs(title = paste(personnel, " - Average IMDb Scores by Genre"), x = "Genre", y = "Average IMDb Sc
    theme(axis.text.x = element_text(hjust = 1)) +
    coord_flip()

  plot_list[[personnel]] <- p
}

grid.arrange(grobs = plot_list, ncol = 4, nrow = ceiling(length(plot_list) / 4))
```



As mentioned above, regarding country distributions may be unreliable due to imbalanced country sample size. However, for genre preferences, some of which tend to rank high in average IMDb scores across different personnel categories (eg., history, western). This suggests that introducing interaction terms for specific pairs could potentially be valuable for the model. (top_director-adventure, top_actor1-history, top_actor2-history, top_actor3-war, top_cinematographer-western, top_production_company-western, top_distributor-history)

Regression Analysis Overview (heteroskedasticity, collinearity) Heteroskedasticity test

## Heteroskedastic predictors for data frame 8:
##  [1] "movie_budget"           "duration"               "aspect_ratio"
##  [4] "nb_news_articles"       "actor1_star_meter"      "actor2_star_meter"
##  [7] "actor3_star_meter"      "scifi"                  "thriller"
## [10] "drama"                  "war"                    "crime"
## [13] "movie_meter_IMDBpro"    "biography"              "sci-fi"
## [16] "history"                "family"                 "top_actor1"
## [19] "top_production_company" "maturity_rating.PG"     "maturity_rating.R"
## ========================================================
```

Heteroskedasticity is present in the dataset. The non-constant variance test has identified several predictors that show signs of heteroskedasticity when plotted against the target variable (likely IMDb score). Key heteroskedastic predictors include:

- Continuous variables: movie_budget, duration, aspect_ratio, nb_news_articles, actor star meters, and movie_meter_IMDBpro. Genre variables: scifi, thriller, drama, war, crime, biography, history, and family.
- Categorical variables: top_actor1, top_production_company, maturity ratings (PG and R), and country (UK).

These flagged predictors suggest that the variance of the residuals changes across their range when predicting the target variable. This heteroskedasticity should be considered when building predictive models, as it may affect the efficiency and reliability of standard regression techniques.

simple linear regressions between Y and each predictor xi

## ========================================================
```

Based on the p-values you provided, the variables with the most linear predictive power for predicting imdb_score (p-value < 0.01) are: movie_budget, duration, nb_news_articles, actor1_star_meter, action, horror, biography, comedy, maturity_rating.PG, maturity_rating.R, country.UK, country.USA, scifi.

These variables are statistically significant predictors, with duration showing the highest R-squared value, indicating it has the strongest linear predictive power among the listed variables.
